About Reflection ZFE

The Reflection ZFE web client provides browser-based HTML5 access to 3270, 5250, VT, UTS, and T27 host applications. The Reflection ZFE product eliminates the need to touch the desktop; no software to deploy, patches to apply, or configurations to make. You can provide platform-independent user access to all your host applications.

The web client operates with complete session protection using SSL/TLS to secure communication with your mainframe systems.
Release Notes

Reflection ZFE version 2.3.5 released April 2019. These release notes list the features and known issues in this release and information on how to obtain the product. Reflection ZFE provides terminal emulation for 3270, 5250, VT, ALC, UTS, and T27 host types, while requiring only an HTML 5-capable browser.

Management and Security Server Release Notes

Host Access Management and Security Server version 12.5.5 released with Reflection ZFE 2.3.5. MSS release notes are available here.

NOTE: The End User License Agreement (EULA) is available in English, Spanish, French, Italian and German in the <install location>\licenses directory.

What’s New

This is the fifth interim release of Reflection ZFE since the 2.3 release in July 2018. The list of new features and fixes includes everything included in this release as well as the 2.3 release with their release versions noted. All releases are cumulative and this 2.3.4 release contains everything released in all prior releases. You can see release notes for previous releases here.

NOTE: As of the 2.3 release, Reflection ZFE uses activation files to enable host access and product functionality. After installing, open the MSS Administrative Console (Configure Settings > Product Activation) to activate. An activation file follows this format: activation.<module_name>.jaw.

• Features and fixes include:
  — In this release you can now deploy the session server to a Docker container. The ZFE install package contains an initial Dockerfile and accompanying application jar file to get you started using the session server in containers. (2.3.5)
  — There is a new JavaScript API. Using the ZFE JavaScript API you can embed the web client in your own web site. (2.3.5)
  — The documentation contains a new Deploy section, which provides information on using Docker, determining the size of your deployment, and an High Availability Deployment Blueprint describing how to deploy ZFE in a highly available, scalable, and secure manner. (2.3.5)
  — With this release the ZFE installation program verifies that the available memory and number of CPU cores meet the minimum system requirements. (2.3.4)
  — You can now update, modify, and extend the presentation of the ZFE web client using your own HTML, CSS, or JavaScript code using the new extension feature. Read more about it here. (2.3.4)
  — Using IND$File you can now enter the path to a file and initiate a manual transfer (2.3.3)
  — Improved Keyboard Mapping User Interface (2.3.2)
  — Added ability to append screen captures to an existing screen capture file (2.3.2)
— Enhancements to the FTP batch file transfer feature, including copying lists and items (2.3.2)
— Improved handling of function keys in Internet Explorer (2.3.2)
— You can transfer multiple files in one operation using the new FTP batch file transfer option (2.3.1)
— Reflection ZFE Airlines Edition adds support for ALC host types (2.3)
— Easier and more user friendly certificate and key store management (2.3)
— Reflection ZFE now includes OpenJDK: Azul Zulu as a replacement for the Oracle JDK (2.3)
— New font options, including resizing, zero customization, and scaling functionality (2.3)

• Multiple bug fixes

Known Issues

Micro Focus Technical Support is always available to help you with any issues you may encounter in Reflection ZFE.

• Reflection ZFE and replication

Management and Security Server (MSS) provides the ability to replicate Reflection ZFE settings, including user customizations, macros, and session servers. In order for the list of Reflection ZFE session servers in the MSS Administrative Console to reflect changes made on other MSS servers, you must restart MSS.

Unresolved issues from previous releases are listed in Technical References under Known Issues.

Installing the Product

Read Walking through ZFE for specific system and installation requirements and helpful tips.

Contacting Micro Focus

For specific product issues, contact Micro Focus Support (https://www.microfocus.com/support-and-services/).

Additional technical information or advice is available from several sources:

• Product documentation, Knowledge Base articles and videos - see Support for Reflection ZFE.
• The Micro Focus Community pages – see Micro Focus Communities.

Reflection ZFE provides zero-footprint terminal emulation that delivers browser-based HTML5 access to 3270, 5250, VT, UTS, ALC and T27 host applications without the need to touch the desktop or install and manage Java runtime environments. A centralized administrative location reduces IT costs and desktop management time while efficiently providing and delivering host access to end users. Communication is protected using HTTPS, SSL/TLS, and SSH security.

Next steps

- Learn how ZFE works
- Evaluate ZFE
- Walk-through ZFE

How it works
Reflection ZFE components

Familiarize yourself with how ZFE uses its three components:

- **Host Access Management and Security Server**
  The Host Access Management and Security Server (MSS) provides an Administrative Console, a web-based centralized location where you can add, edit, and delete terminal sessions. MSS is part of the broader Micro Focus story and is compatible with other Micro Focus products.

- **Session Server**
  The session server is an NT service or UNIX daemon that provides the engine that runs host sessions. Multiple session servers can serve up tens of thousands of sessions and provide efficient and rapid access to your host data.

- **Web Client**
  The web client is the web-based terminal emulator where your users can easily access authorized sessions from any platform and from any location.
  The Web client provides macros, keyboard and color mapping, on-screen keyboard, copy/paste functionality, host-initiated screen updates, and file transfer capabilities.

Administrator and end user roles

Both administrator and end user roles are represented in ZFE’s documentation and work flow. The administrator creates sessions, assigns users to those sessions, and sets user preferences. The end user accesses his assigned sessions, interacts with the web client to connect to the host, and accomplishes his tasks.

Browser and operating system support

Reflection ZFE is a 64-bit based product and supports Google Chrome, Mozilla Firefox, and Microsoft Internet Explorer and Edge browsers. The use of Docker containers makes vertical and horizontal scaling possible and supports cloud-based technologies. A complete list of supported platforms and other installation requirements is available in Evaluation system requirements.

Security considerations

When you open up your legacy hosts to users outside the corporate firewall - business partners, remote users, mobile sales personnel, and others - you need to shield your information from known security threats. With Reflection ZFE, you can provide secure web-to-host access to all your users, whether they’re around the corner or around the world. Reflection ZFE, along with the MSS, provides HTTPS connections and a variety of authorization and authentication options.

Reflection ZFE supports the TLS and SSH protocols to protect mission-critical data. To secure your passwords and other sensitive data, use the HTTPS protocol, which provides TLS encryption.

Reflection ZFE can be connected securely to the browser, the host, and the management server. See Securing connections for information on securing those connections.

Getting ZFE

You can download and evaluate ZFE.
Evaluation system requirements

To successfully install and evaluate ZFE your system needs:

- 8 GB of memory
- A supported browser and operating system.

See System Requirements for a comprehensive list of supported environments.

If you don’t have our software yet, visit https://www.microfocus.com/products/reflection/zfe/trial/ and fill out an evaluation request form. You’ll be sent an e-mail message with instructions to download and install an evaluation copy of Reflection ZFE good for 120 days. Using this evaluation copy you can open and close host sessions and maintain 5 active host connections at a time. The trial site has all the information you need to take the next step.

The Micro Focus download site contains the compressed files necessary to install all supported platforms, including the Windows connector. Different activation files will enable different editions/plforms of Reflection ZFE.

NOTE: MSS uses activation files (activation.jaw) to enable product functionality. The ZFE install program contains the needed activation file and it is activated as part of the install process.

Basic install

The following instructions provide you with the basic default installation. This means that all components are installed locally and are using default ports. With this installation in place you can follow the walk through and familiarize yourself with ZFE and MSS.

1. From the Micro Focus download site, download your product install package. The package includes support for all supported platforms.

2. Following the install program prompts, install Reflection ZFE and Management and Security Server (MSS).

NOTE: During a basic install a self-signed certificate is used to ensure secure connections. When you move into a production environment you can provide your own certificates.

Now you can take the next step; walking through ZFE.

Walking through ZFE

The following instructions are based on a basic default installation. This means that all components are installed locally and are using default ports. With this installation in place you can follow the steps and familiarize yourself with ZFE and MSS.

See Deploying for information about installing into production environments and different production scenarios.
Steps you will follow

- Open the MSS Administrative Console.
- Create and launch a new session. This opens a new browser window and the web client Connection panel displays.
- Configure settings, including key and color mapping, enabling hotspots and macros, and other connection and user preference options.
- Assign users to sessions.
- Provide access to sessions.

Open the Administrative Console

1. In a Windows environment, from the Start menu, under Micro Focus Reflection ZFE, click Administrative Console or open the URL for the administrator login page in your web browser. The URL uses this format: https://myserver.mycompany.com:443/adminconsole.
2. If you connect using HTTPS and your server has a self-signed certificate, your browser will warn you about the certificate you created. This is expected behavior; you can accept the self-signed certificate or choose to proceed and the administrator login page will open. After you purchase a CA-signed certificate or import the self-signed certificate into your certificate store, these warnings will stop.
3. The administrative account has a built-in password, admin. Log on as an administrator using this password or by entering the password that you specified when you installed MSS.

Create a new session

You add, edit, and manage sessions from the Manage Session panel of the Administrative Console. When you add a session it becomes available in the session list of this panel.

- From the Manage Sessions panel, click Add to create a new session
Manage Sessions - Add New Session

Configure Session

Product
Reflection ZFE

Session name *

ZFE Session Server Address *
https://anon.zfe-ci.attachmate.com/zfe

2. If it is not already selected, select Reflection ZFE, enter a session name, and click Launch to open a new browser window and start configuring the session for the server listed at the ZFE server address.

Configure settings and connect

You configure different settings and options for the session, as well as connect to the host, in the web client browser window.

1. On the Connection panel, for the session you are creating, choose the host type, and enter the name and port number of the host.
2. Connection settings vary depending on the type of host connection. For detailed descriptions of the setting options for each host type, see the web client help. Setting options include mapping keystrokes to selected keys, mapping host colors to match your preferences, and recording session macros.

   **Mapping keys**

3. To map keys to selected keys, open **Key Mappings**.

4. Press the key or key combination you want to use to trigger the selected action.

   **Key Mappings**

   ![Key Mappings](image)

5. From the **Action** drop down list select the action you want mapped to the selected keystroke. Click **✓** to complete the key mapping. You can continue adding and mapping keys.

6. Click **Save** to complete mapping keys.

   **Change host colors and other options**

7. From the left navigation panel, you can map host colors, set font and keyboard options, and enable hotspots by opening the **Display** panel. Color choices are specific to each session.

8. Open **User Preference Rules** to extend configuration options to your end users.

9. Click **Exit** to return to the Administrative Console browser window to authenticate and assign users to sessions.

**Configure authentication and assign users to sessions**

Now that sessions are created, you need to grant users access to those sessions. Users are authenticated and assigned to sessions in the MSS Administrative Console. A user can be assigned to multiple sessions.

1. Authentication and authorization validates the identity of a user and the method you want to use to map sessions to individual users or groups of users. From the left navigation panel, select **Configure Authentication**.

2. Choose an authentication method. Your options change depending on your selection.
Configure Authentication

3. There are descriptions of the various options in the MSS documentation. Click ?.
4. Click Apply to complete the process.
5. Open Assign Access to map sessions to individual users or groups of users.
6. Map the sessions to the users you want to access the sessions and click **Apply**. You can also choose to allow users to inherit access to sessions and to the Administrative Console.

**Provide end users access to sessions**

The final step is to share a URL to your session server with your users. The URL usually looks something like this:

https://myserver.mycompany.com:port/zfe

When they access the session server, your users will be prompted to log in as needed, and then they will be given access to their assigned sessions.

In more complex deployments the URL you provide will be to a load balancer and not the session server itself. These links are often embedded in corporate portals or other proprietary web sites.

Planning for Deployment

How many session servers do you need to deploy? How many MSS servers? Are there other considerations? In this section learn how to optimize your session server and MSS server deployment.

In this section:

- Scaling and High Availability
- Deployment Options
- Using Load Balancers
- Terminal ID Manager

Scaling and High Availability

Determining how many session servers and MSS servers you require to meet your needs is the first task in planning for deployment. Whatever your needs ZFE can be deployed to provide both capacity and high availability.

Your solution depends on your needs, but read HA Deployment Blueprint for an illustration of a scalable and highly available deployment.

The main questions that you need to answer are:

- How many concurrent host session will my users need to run?
- How many users will be using the system?
- How available does the system need to be in the event of a failure in various areas of the system?

NOTE: It is important to remember that high availability, along with its advantages, comes with extra complexity and maintenance. If you don’t require a large number of host sessions or if downtime is acceptable in your environment, you can simply refer to the system requirements, start with a single server, and then build out as needed.

Scaling

Scalability is a system’s ability to handle various amounts of load. To increase capacity, a system can be scaled up (vertically) by running on a more powerful server or scaled out (horizontally) by adding more servers or nodes.

There are trade offs to consider with each case:

- **Scaling up** offers the simplicity of fewer servers, however it also increases the risk of a significant failure if a server goes down.
- **Scaling out** involves more servers but spreads the risk over many servers so when one goes down, a smaller number of users are affected.
Due to the increased resiliency, we recommend scaling out by adding more servers or nodes when increasing capacity.

**High Availability**

High availability (HA) is a system’s ability to continue providing services when a failure occurs somewhere in the system. HA is achieved by adding redundancy to key components of the system.

**NOTE:** This guide discusses providing high availability of the core ZFE services, however true high availability relies on redundancy at many layers in all areas of the systems, which is beyond the scope of this document.

High availability in ZFE is achieved by:

- Deploying enough session servers and MSS servers to provide the needed capacity, with headroom (free capacity) for failures
- Ensuring proper headroom so when a server does fail and the load fails over to the remaining servers, they are not compromised by the extra load
- Using load balancers to distribute the load and direct users to other servers in the event of a failure

See the [HA Deployment Blueprint](#) section for an illustration of how to accomplish these requirements.

**Session Server Sizing**

The number of session servers you need is determined by the number of concurrent host sessions you are running. Host sessions generate more load on the session server than users do, therefore we are focusing on the number of required host sessions instead of the number of users.

<table>
<thead>
<tr>
<th>Number of concurrent heavily used host sessions</th>
<th>Number of session servers required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Up to 2000 (No high availability)</td>
<td>1 session server</td>
</tr>
<tr>
<td>Up to 3000 (high availability)</td>
<td>2 session servers</td>
</tr>
<tr>
<td>More than 3000 (high availability)</td>
<td>(Number of host sessions needed) / 2000 (Minimum of three)</td>
</tr>
</tbody>
</table>

- “Heavily used” is defined as each user navigating to a new screen approximately every 5 seconds.
- A session server, running the recommended 2000 host sessions, has built in headroom to handle 1000 additional host sessions in the event of a failover scenario.
- A minimum of two session servers are required for high availability.

**MSS Server Sizing**

The number of MSS servers you need is determined by the number of concurrent users.
A MSS server has built-in headroom for an additional 5000 users in the event of a failover scenario.

- A minimum of 3 MSS servers are required for high availability.
- Beyond 3, an odd number of MSS servers are required for high availability due to the need for a database quorum.

Deployment Options

You can deploy session servers in one of two ways:

1. Using the traditional method of installing each session server onto a dedicated server
2. Using Docker to run each session server in a container. Docker provides a number of benefits including more flexibility around how many session servers you can run on a single server. See Using ZFE with Docker for more information.

Using Load Balancers

You will need to provide load balancers for both session servers and MSS. There are common settings you should be aware of:

- Load Balancing Algorithm - The algorithm determines which server to send new traffic to. We recommend “Least Connections” or something similar. Verifying this setting is properly distributing load is essential for overall system stability. If the load balancer is not configured properly or working effectively, you run the risk of an individual server becoming overloaded.
- Session Persistence (Affinity/Sticky Sessions) - This is the ability to send the same user to the same server through multiple requests. Both the session server and MSS are stateful applications and require sticky sessions to be enabled on their load balancers. Noted below.
- Health Check Endpoint - This is the URL on the target service that is used to determine if the instance is healthy and should remain in service. Each server type provides its own health URL.

The HA Deployment Blueprint section provides recommended setting values for each load balancer.

TLS/SSL options

There are three typical options for handling TSL/SSL on a load balancer. The option you choose depends on your needs.

Your certificate needs to be installed on the load balancer in the first two options. The third option, TLS passthrough, does not require a certificate on the load balancer. The HA Blueprint uses TLS Bridging to provide end-to-end TLS while still allowing cookie-based persistence. The options are:

- TLS Termination/Offloading - This option ends the HTTPS connection at the load balancer and continues to the service by means of HTTP.

<table>
<thead>
<tr>
<th>Number of concurrent users</th>
<th>Number of MSS servers required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Up to 10,000 (No high availability)</td>
<td>1 MSS server</td>
</tr>
<tr>
<td>Up to 30,000 (high availability)</td>
<td>3 MSS servers</td>
</tr>
<tr>
<td>More than 30,000</td>
<td>(Number of users needed) / 10,000 (must be an odd number)</td>
</tr>
</tbody>
</table>
- **TLS Bridging (Re-encryption)** - This option ends the HTTPS connection at the load balancer and re-establishes a new HTTPS connection between the load balancer and the service. This provides end-to-end TLS while still allowing the load balancer to inject a cookie for session persistence.

- **TLS Passthrough (Required for X.509)** - The load balancer proxies the TLS connection without decrypting it. The downside to this option is that since no cookie can be injected, persistence must be based on source IP or something similar.

**TLS/SSL with X.509 Single Sign-On**

When using X.509 authentication, the TLS Passthrough option is required on ZFE and MSS load balancers since client certificates must be presented to the servers in the backend. Because TLS Passthrough is required, you will need a non-cookie based method for session persistence, such as source IP for both the session server and MSS load balancers. This is necessary because with TLS Passthrough there is no chance for the load balancer to decrypt the connection to set or even view a cookie.

**Terminal ID Manager**

The Terminal ID Manager does not currently support HA. You can set up a passive server, but the state of the IDS will not be replicated from the active server. When the active server is unavailable, you will still be able to access the passive server, but the IDs will not maintain their current state.

**HA Deployment Blueprint**

The following is an example of how to deploy ZFE in a highly available, scalable, and secure manner. While the details of every deployment will differ, the goal here is to provide a known good starting point and to answer common deployment questions.

**Architecture**

This deployment consists of:

- Session server load balancer
- Two session servers
- MSS load balancer
- Three MSS servers
- Terminal ID Manager
• LDAP or identity management server
• Host/mainframe

Deployment benefits

With this example, you will see:

• Capacity for up to three thousand host sessions and the ability to be scaled as needed
• High availability of key services; minimizing single points of failure and distributing load by means of load balancers
• The ability to handle the failure of one session server and one MSS simultaneously without a significant drop in the performance of the web client, due to built-in headroom
• Authentication and authorization options for MSS
• Secure communication through HTTPS

Steps when deploying

We recommend you follow these steps when deploying:

1. Learn about the basics of deployment
2. Provision resources based on system requirements and sizing guidelines
3. Install MSS and create a cluster
4. Configure MSS load balancer
5. Install session servers
6. Configure session server load balancer
7. Verify deployment
8. Configure single sign-on (optional)
9. Configure Terminal ID Manager (optional)

You’ve learned about the basics of deployment, system requirements and sizing guidelines in previous sections.

Installing MSS

Install three MSS servers and configure each of them for replication. There is documentation that can step you through the process:

1. Open ports on the firewall. Ports used by MSS and ZFE are listed here
2. Install MSS and then the ZFE components for MSS by running the ZFE install program on each MSS server.
3. Configure each server for replication.
4. On each MSS server, configure general settings, security settings, and other settings as required.

5. In each MSS container.properties set the management.server.callback.address property to be a resolvable address for the specific MSS server. (for example, mssserver1.mydomain.com) With this property set the MSS server can provide a callback address to the session server when editing sessions and with a load balancer in front of MSS.
Configuring a MSS load balancer

As described in the Using Load Balancers section of this guide, use these values when configuring the MSS load balancer:

- **Load balancing algorithm**: Least Connections (or something similar)
- **Session persistence**: Enabled - use existing JSESSIONID cookie

Because cookies are not stored in the session server when it is acting as a client to MSS, the MSS load balancer must use either the existing JSESSIONID cookie or source IP (or something similar) for persistence.

- **Health check endpoint**: `https://<mss-server>/`
- **TLS**: Configure TLS and install certificates as needed.

Installing ZFE session servers

Install two or more session servers.

For each session server:

1. Open ports on the firewall. Ports used by MSS and ZFE are listed [here](#).
2. Install the session server. During installation, choose to use a remote MSS server, and enter the MSS load balancer address and port.
3. Import the session server certificate into each MSS server’s trust store: `trustedascj.bcfks`.

| TIP: This is done automatically for you on the MSS server that the load balancer chose during installation, but must be done manually on the other servers. It is best practice to import or verify its presence on each MSS server. |

**Additional resources:**

- Ports used by ZFE and MSS
- Installing ZFE
- Securing the Session Server to MSS

Configuring session server load balancer

Use these values to configure the load balancer:

- **Load balancing algorithm**: Least Connections (or something similar)
- **Session persistence**: Enabled - use JSESSIONID or a new cookie. Unlike the MSS load balancer you are not required to use the existing JSESSIONID cookie.
- **Health check endpoint**: `https://<session-server>/zfe/actuator/health`
For the session server in particular, be cautious when you are configuring how to determine a node has failed and what to do once it has failed. If there are users still connected to the instance, those users may lose their host connections. To avoid marking an instance as failed too early, consider increasing timeouts or retries. Some load balancers provide a “drain mode”, which allows existing users to stay connected, but will direct new users to other instances.

- **TLS**: Configure TLS and install certificates as needed.

### Verifying the installation

After installing and configuring all components, you’ll want to:

- Log into the MSS Administrative Console (through the MSS load balancer).
- Navigate to Manage Sessions > Add a New Session and create a test session. When you add a new session, specify the session server load balancer for the session server address.
- Assign the test session to a test user.
- Log into the session server as the test user, through the session server load balancer.
- Verify that the assigned session is available, opens, and can connect.

### Configuring Single Sign-on (optional)

Following are a few additional considerations when configuring single sign-on in an high availability deployment.

**SAML (Security Assertion Markup Language)**

The MSS Administrator Guide has **SAML Authentication** instructions.

1. Import the MSS load balancer certificate into each MSS `servletcontainer.bcfks` as a trusted certificate.
2. Update the `management.server.url` in each MSS `container.properties` file to use the MSS load balancer address.
3. Restart the MSS servers.
4. Log on to the Administrative Console of the active MSS server to configure the SAML Authentication.
   
   Confirm that the MSS load balancer DNS is used in the **Assertion consumer service prefix URL** field and add the MSS load balancer and ZFE load balancer DNS to the SAML whitelist.

**X.509**

The MSS Administrator Guide has **X.509 Authentication** instructions.

In each case the certificate used must have a Subject Alternative Name (SAN) that contains all MSS server DNS names, along with the load balancer DNS name.

1. Verify that the firewall on the MSS server allows HTTP traffic on the mutual authentication port; 8003 is the default.
2. In each MSS:
   - Replace the certificate of the servlet-engine entry in the `servletcontainer.bcfks` files.
   - Replace the certificate of the system entry in `system.bcfks` files.
3. Import the certificate into each ZFE’s:
   - `trustcerts.bcfks` file as a trusted certificate.
4. Restart the MSS and ZFE servers.
5. Configure both the MSS and ZFE load balancers for TLS passthrough.
6. Configure X.509 authentication as documented here: How to configure X.509 authentication.

Installing ZFE

Keep these things in mind when installing Reflection ZFE.

- **Activation files**
  Activation files (activation.jaw) are used to enable product functionality. For example, The ZFE install package contains the needed activation file to enable communication between ZFE and MSS. It is typically activated as part of the install process. Activation files are downloaded from the Micro Focus download site and are specific for the different editions and platforms supported by ZFE. To work in a production environment, activation is required.

  If activation was not part of the installation, you need to open the Administrative Console and complete the activation process (Configure Settings > Product Activation). See Upgrading from previous versions for information on handling activation files when you upgrade.

- **IIS Reverse Proxy with ZFE**
  If you plan on using the IIS Reverse Proxy with Reflection ZFE, read Accessing Reflection ZFE using the IIS Reverse Proxy for prerequisites and configuration instructions.

- **Security**
  Reflection ZFE supports TLS and SSH protocols to protect mission-critical data. To secure your passwords and other sensitive data, you should require browsers to use the HTTPS protocol. For more information on TLS/SSL, see....

Installing on different platforms

**ZFE and Java**

The Reflection ZFE session server requires a Java JDK version 8 or higher and MSS requires a Java JRE version 8 or higher. This Java requirement is met during installation, except for systems, such as Linux on System Z that require an IBM JDK. Information on using the `nojdk` option is available under Installing on z/Linux.

Both Reflection ZFE and MSS require that the Java installation support unlimited strength encryption. More information is available on the Java web site.

If necessary, you can use the environment variables specified in the `nojdk` option and `INSTALL4J_JAVA_HOME_OVERRIDE` to specify a specific Java installation.

**Windows**

A basic Windows installation is described in Getting ZFE.
UNIX

- You must either install as “root” or use a user account with root privileges to complete successfully. When the installation has successfully completed, the installed application can be started and managed by “root” or someone running as ‘root’.
- If you are running on Linux platforms, follow these steps to set the session server to start automatically when your system first boots up.
- Elevated privileges are needed to open any application ports lower than 1024. Reflection ZFE will not start using a lower port number unless you have system privileges to open low numbered ports.
- You can use the chmod command to assign application privileges to users other than root.
- If you are installing on a headless Linux system and there are no fonts installed on the system, you may encounter this font-related error: java.lang.Error: Probable fatal error: No fonts found. Ensure that fontconfig or at least one font is installed on the system in order to proceed with the installation.

z/Linux (SUSE E11.x and RHEL 6.x)

For systems, such as Linux on System Z, that require an IBM JDK, you can use the “nojdk” installer media, which does not include a bundled JDK.

- The installation must be able to locate a Java executable to start. If a Java executable cannot be found by the installer, then you can set the INSTALL4J_JAVA_HOME environment variable to refer to a Java installation’s bin directory.
- When started, the installation program will automatically search for version-compatible JDKs on the system. If more than one JDK is found, a list is displayed from which you can choose. If only a JRE is found on the system, you can continue with the installation, but the Reflection ZFE server will not run correctly until you have updated the wrapper.java.command property located in sessionserver/container.conf to refer to a JDK installation.

If necessary, you can use the environment variables named above and INSTALL4J_JAVA_HOME_OVERRIDE to specify a specific Java installation.

Upgrading from previous versions

**WARNING:** If you are upgrading, it is important that you remove any activation files from MSS associated with prior versions of Reflection ZFE. Leaving obsolete activation files in place may result in limited access to sessions.

It’s best to back up any previous work before you upgrade.

1. From the Micro Focus download site, download the install package and activation files for the version you are upgrading to.
2. Remove any activation files from MSS associated with prior versions of Reflection ZFE. Leaving obsolete activation files in place may result in limited access to sessions.
3. Install Reflection ZFE.
4. If not handled during the installation process, install the new activation file or files into MSS using Administrative Console > Configure Settings > Product Activation.
Additional configuration

To continue using server side events or other customizations created in previous versions of ZFE, there are some minor manual steps to undertake after upgrading:

- **Server-side Events** - Copy your server-side event JAR files located in `/webapps/zfe/WEB-INF/lib` to `/microservices/zfe/extensions/server`.

- **Client extensions** - Copy the contents of `webapps/zfe/custom` to `/microservices/zfe/extensions/client`. Re-enable extensions.

Troubleshooting the Installation

To complete a successful installation, make sure that you have taken care of these common issues:

1. **Are the activation files installed and activated in the Administrative Console?**
   MSS uses activation files to enable product functionality. With your installation you received an activation file associated with the type of host you are connecting to. For example, if you are licensed for the Unisys Edition, if not handled as part of the install process, you will need to open the Administrative Console, go to Configure Settings > Product Activation and verify that both the Reflection ZFE Unisys activation file is in place.

2. **Is MSS configured for HTTPS?**
   Connect to the system where the Administrative Server is installed and log in to the Administrative Server. In the Administrative Console, open the Security Setup section and note the protocol selection.

3. **Verify that both MSS and Reflection ZFE are using trusted certificates.**
   MSS imports certificates and private keys to `C:\ProgramData\Micro Focus\MSS\MSSData\certificates`.
   If you are not using trusted certificates, have you configured Reflection ZFE to run using HTTP?

4. **Are your connection properties configured properly?**
   In the unlikely event that you have to verify connection information, the `container.properties` file for both the management component and the Reflection ZFE session server contains the connection properties needed to make the Reflection ZFE to MSS connection as well as the browser to Reflection ZFE connection.
   You can find the file in the Reflection ZFE installation at `<install-dir>/sessionserver/conf/container.properties`.

5. **Install does not complete on UNIX or Linux platforms**
   The Reflection ZFE install program may stall on UNIX or Linux systems, particularly headless ones. This stall is caused by an insufficient amount of entropy in the system, typically due to a lack of interaction with the operating system’s UI (or lack of UI).
   To remedy the issue:
   1. Stop the installation process.
   2. On the installer’s command line, prepend –J to the Java System property: `./reflectionzfe-xxxxx-linux-x64.sh -J-Djava.security.egd=file:///dev/urandom`
   3. Run the installation program containing the added argument.
Ports used by ZFE and MSS

Configure your firewall to allow connections on the following TCP listening ports:

<table>
<thead>
<tr>
<th>Component</th>
<th>Default Port Numbers</th>
</tr>
</thead>
<tbody>
<tr>
<td>ZFE session server</td>
<td>• 7070 - HTTP</td>
</tr>
<tr>
<td></td>
<td>• 7443 - HTTPS</td>
</tr>
<tr>
<td>MSS</td>
<td>• 80 - HTTP</td>
</tr>
<tr>
<td></td>
<td>• 443 - HTTPS</td>
</tr>
<tr>
<td></td>
<td>• 7000 - Database replication</td>
</tr>
<tr>
<td></td>
<td>• 7001 - Database replication TLS</td>
</tr>
<tr>
<td></td>
<td>• 8003 - X.509 Trusted subsystem</td>
</tr>
<tr>
<td></td>
<td>• 8761 - Service Registry</td>
</tr>
</tbody>
</table>

Both the Reflection ZFE and the MSS Administrative Server ports can be changed depending on your network needs. To modify the Reflection ZFE session server ports, see How to Change Ports.

Configuring your Deployment

When you begin to configure a deployment of ZFE there are a number of post-installation options to consider, as well as security concerns.

- How to Adjust Session Timeout Values
- How to Set Up the Terminal ID Manager
- How to Set Up Metering
- How to Start and Stop Services Automatically
- How to Change Ports
- How to Set Up Automated Single Sign-On for Mainframe
- How to configure X.509 authentication
- How to configure single sign-on through IIS
- How to use the IIS Reverse Proxy with ZFE
- How to enable FIPS level security
- Securing connections

How to Adjust Session Timeout Values

The default timeout value for an inactive Reflection ZFE session is 30 minutes. This means that a session that was not logged out and has had no activity will close after 30 minutes. You can configure this setting on the server.

1. Open `<install directory>/sessionserver/microservices/zfe/service.yml`.
2. Adjust the session timeout value in the `env` section of the file:
- name: server.servlet.session.timeout
  value: <desired-time-in-seconds>
- name: server.servlet.session.cookie.max-age
  value: <desired-time-in-seconds>

**TIP:** The indentation formatting is important.

3 Restart the server.

### How to Set Up the Terminal ID Manager

The Management and Security Server provides a Terminal ID Manager to pool terminal IDs, track ID usage, and manage inactivity timeout values for specific users, thus conserving terminal ID resources and significantly reducing operating expenses.

The Terminal ID Manager Add-On requires a separate license.

Before you configure the Terminal ID Manager for Reflection ZFE, verify that you have this option enabled for MSS. There are complete instructions in the [MSS Installation Guide](#).

**TIP:** If MSS and Reflection ZFE are installed on the same machine and using port 80, no additional configuration is needed.

#### Configuring Terminal ID Manager for Reflection ZFE

To configure the Terminal ID Manager for Reflection ZFE, you must provide the correct address to the Terminal ID Manager.

1 Open the `sessionserver/conf/container.properties` file.

2 Update `id.manager.server.url=http://localhost:80/tidm` to reflect the address of the Terminal ID Manager configured in Management and Security Server.

3 Restart the Reflection ZFE Session Server.

### How to Set Up Metering

The Management and Security Server provides metering capabilities to monitor Reflection ZFE host sessions.

Before you configure metering for Reflection ZFE, verify that you have metering enabled for MSS. There are complete instructions in the [MSS Installation Guide](#).

In Reflection ZFE metering is set globally for all emulation sessions created by the Reflection ZFE session server. Settings are configured in the `sessionserver/conf/container.properties` file.
## Table 3-1 Metering options

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metering.enabled</td>
<td>Turns metering on or off, with a value of &quot;true&quot; or &quot;false&quot;. Any value other than &quot;true&quot; turns metering off.</td>
</tr>
<tr>
<td>metering.host.required</td>
<td>Determines whether the session can connect to the host even if the metering server cannot be contacted. &quot;True&quot; means that session connections will fail if the metering host is unavailable. &quot;False&quot; means that session connections will still work even if the metering host is unavailable.</td>
</tr>
<tr>
<td>metering.server.url</td>
<td>Specifies the name or address of the metering server, the port, the protocol, and the webapp context. The syntax is &quot;host:port</td>
</tr>
</tbody>
</table>

Example additions to sessionserver/conf/container.properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metering.enabled</td>
<td>true</td>
</tr>
<tr>
<td>metering.host.required</td>
<td>false</td>
</tr>
<tr>
<td>metering.server.url</td>
<td>10.10.11.55:80</td>
</tr>
</tbody>
</table>

**NOTE:** In the event that all licenses are in use and you attempt to make a connection, the session will be disconnected. To determine whether the host has disconnected or the metering service has stopped the connection, see the Reflection ZFE/sessionserver/logs/server.log file.

### How to Start and Stop Services Automatically

All server components are installed as services and can be configured to start during installation.

If you are running on Linux platforms, follow these steps to set the session server to start automatically when your system first boots up.

Create a file called zfe containing the following and using your installation directory:

```bash
#!/bin/sh
#
# This script manages the service needed to run the session server
# chkconfig:235 19 08
# description: Manage the Reflection ZFE session server
###BEGIN INIT INFO
# Provides:          zfe
# Required-Start:    $all
# Required-Stop:     $all
# Default-Start:     2 3 4 5
# Default-Stop:      0 1 6
# Description:       Start the Reflection ZFE Session Server
### END INIT INFO

INSTALL_DIR=<enter installation directory>
BIN_DIR=${INSTALL_DIR}/sessionserver/bin
case "$1" in
  start)
    echo "Starting Reflection ZFE Session Server"
$BIN_DIR/server start
RETVAL=0
;;
stop)
echo "Stopping Reflection ZFE Session Server"
$BIN_DIR/server stop
RETVAL=0
;;
status) echo "Current Reflection ZFE Session Server status"
$BIN_DIR/server status
RETVAL=0
;;
restart) echo "Restart Reflection ZFE Session Server"
$BIN_DIR/server restart
RETVAL=0
;;
*)
echo "Usage: $0 (start|stop|status|restart)"
RETVAL=1
;;
esac
exit $RETVAL

Then complete the relevant steps.

Platform          Follow these steps

Linux

1. Copy the file to the /etc/init.d directory.
2. Set the file permission. Run chmod using the value 755. For example, chmod 755 zfe
3. Run chkconfig to add the initialization script. For example, /sbin/chkconfig --add zfe

How to Change Ports

The default ports used by Reflection ZFE are:

Table 3-2  Reflection ZFE and MSS Default Ports

<table>
<thead>
<tr>
<th>Service Type</th>
<th>Default Ports</th>
</tr>
</thead>
<tbody>
<tr>
<td>Session server</td>
<td>HTTP - 7070</td>
</tr>
<tr>
<td></td>
<td>HTTPS - 7443</td>
</tr>
<tr>
<td>Management and Security Server</td>
<td>HTTP - 80</td>
</tr>
<tr>
<td></td>
<td>HTTPS - 443</td>
</tr>
<tr>
<td></td>
<td>Database replication - 7000</td>
</tr>
<tr>
<td></td>
<td>Database replication TLS - 7001</td>
</tr>
<tr>
<td></td>
<td>X.509 Trusted subsystem - 8003</td>
</tr>
<tr>
<td></td>
<td>Service Registry - 8761</td>
</tr>
</tbody>
</table>

To change the default ports:
How to Set Up Automated Single Sign-On for Mainframe

Automated Sign-On for Mainframe is an add-on product to Management and Security Server that enables an end user to authenticate to a terminal emulation client and be automatically logged on to a host application on the z/OS mainframe.

The Management and Security Server Administrator Guide for Automated Sign-On for Mainframe has complete information on configuring this option.

1 Install and configure the Automated Sign-On for Mainframe add-on for Management and Security Server. You can find complete instructions here.

2 After the Management and Security Server setup is complete, open the Administrative Console to add sessions and map users to those sessions. During that process, you can complete the additional configuration needed to implement automated sign-on.

3 A Reflection ZFE macro sends the user's mainframe username and pass ticket to the host application. The user is then automatically logged in. To help create the macro:

   - The Macro API contains the AutoSignon object that provides the methods needed to create a Reflection ZFE login to use with the Automated Sign-On for Mainframe feature.

   - You can also reference the sample macro Automatic Sign-On Macro for Mainframes that uses the AutoSignon object to create a macro that uses the credentials associated with a user to obtain a pass ticket from the Digital Certificate Access Server (DCAS).

How to configure X.509 authentication

X.509 client authentication allows clients to authenticate to servers with certificates rather than with a user name and password by leveraging the X.509 public key infrastructure (PKI) standard.

Typical installations handles this process for you, if needed the manual instructions are as follows:

Prerequisite

### Table 3-3  Changing default ports

<table>
<thead>
<tr>
<th>Component</th>
<th>Instructions</th>
</tr>
</thead>
</table>
| Reflection ZFE session server | - Open `sessionserver/microservices/zfe/service.yml` to modify:  
  - `name : SERVER_PORT`
  - `value: "7443"`
  - `name : SERVER_HTTP_PORT`
  - `value: "7070"`  
  - To turn the port off, set the port value to 0. You can disable your non-secure SSL port by changing the value from 7070 to 0. |
| Management and Security Server | The SSL port MSS uses to make an HTTPS connection is set to 443 by default. If you need to change the port number, start the Management Server. This creates the default `PropertyDS.xml` file. Then, open `PropertyDS.xml` in the MssData directory. Change the value from 443 to the appropriate port number in the section below, and then restart the Management Server.  

```
<CORE_PROPERTY NAME="sslport"> <STRING>443</STRING>
```
Using the procedure described for a manual configuration in Securing the Session Server to MSS verify that a trusted certificate has been installed in the certificate store. The procedure may vary depending on your operating system and browser.

**Basic steps:**

1. Install the signing authorities certificate into MSS and Reflection ZFE.
2. Restart the servers.

**Step 1. Install the signing authorities certificate into MSS and Reflection ZFE**

MSS’s trusted store may already contain your signing authority certificate. This is often the case with well-known certificate signing authorities, and if so, then you can skip this step.

To check:

Open the Administrative Console, click Configure Settings, and open the Trusted Certificates tab. Open Trusted Root Certificate Authorities to see a list of available certificates.

If your certificate is not listed you need to install your signing root CA into MSS and into the Reflection ZFE session server following the prompts and documentation in the Administrative Console.

To install the certificate into the Reflection ZFE session server:

```
In <RZFE_install_directory>/sessionserver/etc import the certificate:
keytool -importcert
-file <cert-file> -alias <alias-to-store-cert-under> -keystore
servletcontainer.bcfks -storetype bcfks -providername BCFIPS -providerclass
org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider -providerpath ../lib/bc-
fips-*.jar -storepass changeit
```

**Step 2. Restart all the servers**

For the configuration to take effect, you must restart all servers.

**Step 3. Configuring X.509 with LDAP fail over in the MSS Administrative Console**

Once the certificates are in place, you can enable X.509 with the Fallback to LDAP authentication option in Management and Security Server Administrative Console | Configure Settings | Authentication & Authorization. See the Administrative Console online help for descriptions of the configuration options.

**How to configure single sign-on through IIS**

This option uses Microsoft IIS web server. This option requires no additional setup as long as you used the Management and Security Server automated installer and chose to integrate with IIS during the installation process. You can find more information on install configurations in the Management and Security Server documentation.

**How to use the IIS Reverse Proxy with ZFE**

If you plan on using the IIS Reverse Proxy with Reflection ZFE, read Accessing Reflection ZFE using the IIS Reverse Proxy for prerequisites and configuration instructions.

**Enabling Reflection ZFE for use with single sign-on through IIS**

To enable Reflection ZFE to work with this authentication method, add the following property in the `<install dir>/sessionserver/conf/container.properties` file:
management.server.iis.url= <url>

The value of this property is the IIS web server address and port along with the / MSS path. For example: http://server/mss. If authentication fails, you may need to remove the domain name in order for the domain credentials to be passed to IIS: http://server/mss.

Using the IIS Reverse Proxy with Reflection ZFE

**NOTE:** To comply with Common Criteria security requirements it may be necessary to place the Reflection ZFE server behind a proxy by following the instructions in Accessing Reflection ZFE using the IIS Reverse Proxy.

To proxy Reflection ZFE through IIS, when using IIS single sign-on, you need to set an additional property in the same `container.properties` file:

`servletengine.iis.url=<url>`

The value takes the same form as the URL above, but uses the Reflection ZFE address. For example: http://server/zfe. It is not necessary to use the short host name form in this URL.

After you have completed this configuration, you choose this authentication option in Management and Security Server Administrative Console | Assign Access. See the Administrative Console online help for descriptions of the configuration options.

How to enable FIPS level security

The Federal Information Processing Standards (FIPS) 140-2 validated cryptographic modules are used by the US federal government as a security regulation standard. Reflection ZFE supports this standard and you can easily enable FIPS mode by editing a file in the session server.

- Open `<install_directory>\sessionserver\microservice\zfe\service.yml`.
- Add the flag `-Dcom.attachmate.integration.container.FIPS.enabled=true` to the appropriate OS specific Java command; for Unix - `start-command`, for Windows - `start-command-win`.
- Restart the server.

Securing connections

Reflection ZFE and Management and Security Server use HTTPS connections and certificates to ensure secure communication between clients, web browsers, and servers.

In this section:

- Introduction
- Securing the Web Browser to the Session Server
- Securing the Session Server to MSS
- Securing the Session Server to the Host
Introduction

Certificates are electronic credentials that are used to verify the identities of individuals, computers, or networks. Certificates are stored in key stores along with private keys that are used to complete secure transactions. Public keys encrypt data then the private key decrypts the data. Together, the public and private keys are known as a key pair. All key store entries are identified using a unique identifier, known as an alias.

Reflection ZFE and MSS use Bouncy Castle as the provider for their key store operations and use the .bcfks (Bouncy Castle FIPS key store) extension for cryptographic files. They are:

- servletcontainer.bcfks - used to securely connect the Reflection ZFE web application to the session server
- trustcerts.bcfks - The Reflection ZFE trust store where trusted certificates for connections between the session server and MSS are stored.

Values you must know

- changeit is the default password
- servlet-engine is the alias of the key pair entry of servletcontainer.bcfks
- bcfks is the keystore format

Tools

- KeyStore Explorer - You can take advantage of the KeyStore Explorer utility to provide a simple user interface to create signing requests (CSR) and import CA-signed certificates into Reflection ZFE.
  - To launch Keystore Explorer on Windows - run \ReflectionZFE\utilities\keystore-explorer.bat as an administrator or with administrative rights.
  - To launch Keystore Explorer on UNIX - run ReflectionZFE\utilities\keystore-explorer.sh as an administrator or with administrative rights.

The utility has an online Help system available to walk you through the user interface.

- Java Keytool - The Java Key and Certificate Management Tool manages a key store of cryptographic keys, X.509 certificate chains, and trusted certificates. It uses a command line interface. The Java Key and Certificate Management Tool documentation is available for both Unix and Windows platforms:
  - Windows (http://docs.oracle.com/javase/8/docs/technotes/tools/windows/keytool.html)
  - Unix (http://docs.oracle.com/javase/8/docs/technotes/tools/unix/keytool.html)

Connections

In a typical Reflection ZFE installation there are three main connection points that you need to consider in regard to security:

- Securing the Web Browser to the Session Server
- Securing the Session Server to MSS
- Securing the Session Server to the Host
Securing the Web Browser to the Session Server

**NOTE:** A connection between the web browser and the session server is secured using a self-signed certificate. There is no further configuration necessary unless you want to replace the self-signed certificate provided with a different certificate.

To replace the certificate:

- Create a Certificate Signing Request (CSR) for Reflection ZFE and send it to the Certificate Authority of your choice. When you receive the signed certificate from the CA, then you:
  - Import the CA-signed certificate/chain into Reflection ZFE for HTTPS
  - Import and trust this certificate in MSS. See [Securing the Session Server to MSS](#) for instructions.

You can accomplish these tasks using either KeyStore Explorer or the Java Keytool command line instructions.

**NOTE:** The key store commands noted here are for a default installation and start at the `sessionserver/etc` directory. If you have installed Reflection ZFE to another location, you must modify the path appropriately.

To configure a non-default key store:

You can use a key store other than the default, `servletcontainer.bcfks`, to store your CA signed certificates.

- Specify the following properties in `container.properties` found here: `../ReflectionZFE/sessionserver/conf`:
  
  ```
  server.ssl.key-store
  server.ssl.key-store-password
  ```

  Where the key store path is set to the non-default key store file name and the key store password is set to the obfuscated value generated by the following command from the `sessionserver` directory:

  ```
  ../java/jre/bin/java -cp ./lib/jetty-util-<version>.jar org.eclipse.jetty.util.security.Password passwordToObfuscate
  ```

  For example:

  ```
  server.ssl.key-store=../etc/custom.bcfks
  server.ssl.key-store-password=OBF:1vn21ugulsaj1v9ii94lsar1ugw1vo0
  ```

How to create a CSR using KeyStore Explorer

**TIP:** You should run the following commands, using administrative privileges, from the `sessionserver\etc` directory.

Open `sessionserver/etc/servletcontainer.bcfks` in KeyStore Explorer. Use the password `changeit`.

To create a CSR you will create a key pair and then generate a certificate request. If you do not need to update certificate information, you can skip creating the key pair and proceed to generating the certificate request.
TIP: The KeyStore Explorer utility has documentation available to aid you in these tasks.

Create a new key pair
1. Select the servlet-engine key pair.
2. From the right-click menu, click Delete and then click Yes to confirm.
3. From the Tools menu, select Generate Key Pair.
4. On the Generate Key Pair dialog box, enter the appropriate algorithm information and certificate details. Click OK.
5. Enter servlet-engine as the alias. Click OK.
6. Enter changeit as the password and click OK.

Generate a certificate request
1. Select the servlet-engine key pair.
2. From the right-click menu, select Generate CSR.
3. Browse to the file location where you want to generate the CSR and enter the file name. Click OK.

How to create a CSR using Java Keytool

Windows
Create Key Pair (replace the dname parameter with your own):

```bash
..\..\java\bin\keytool.exe -genkeypair -dname "CN=zfe-1.microfocus.com, O=Micro Focus, C=US" -alias servlet-engine -keyalg RSA -keysize 2048 -keystore servletcontainer.jks -validity 1095 -storetype jks -storepass changeit -keypass changeit
```

Generate Certificate Request:

```bash
..\..\java\bin\keytool.exe -certreq -alias servlet-engine -keystore servletcontainer.jks -file cert_request.csr -ext ExtendedkeyUsage=serverAuth -storetype jks -storepass changeit
```

UNIX
Create Key Pair (replace the dname parameter with your own):

```bash
../../java/bin/keytool -genkeypair -dname "CN=zfe-1.microfocus.com, O=Micro Focus, C=US" -alias servlet-engine -keyalg RSA -keysize 2048 -keystore servletcontainer.jks -validity 1095 -storetype jks -storepass changeit -keypass changeit
```

Generate Certificate Request:

```bash
../../java/bin/keytool -certreq -alias servlet-engine -keystore servletcontainer.jks -file cert_request.csr -ext ExtendedkeyUsage=serverAuth -storetype jks -storepass changeit
```

After you receive the certificate from the CA, you will import the certificate into Reflection ZFE.
How to import a CA-signed certificate into Reflection ZFE

For both KeyStore Explorer and the Java Keytool, if the CA Reply contains separate root and intermediate certificate files, import the root certificate into the keystore first, followed by the intermediate certificate.

Using KeyStore Explorer

1. Open `servletcontainer.bcfks` in KeyStore Explorer. Use the password `changeit`.
2. If separate root and intermediate certificate files are available, from the tool bar, select Import Trusted Certificate to import certificates.
3. Select the `servlet-engine` key pair. Right-click and select Import CA Reply to import the file into the key pair.
4. If prompted, enter the password, `changeit`.
5. Browse to the location where the CA Reply file is stored, select the file, and click Import.

Using Java Keytool

These examples use keytool commands at the `sessionserver/etc` directory.

Windows

Import Root CA and intermediate certificates

```bash
..\..\java\bin\keytool.exe -importcert -alias rootca -trustcacerts -file <RootCA.cer> -keystore servletcontainer.bcfks -storetype bcfks -storepass changeit
```

```
..\..\java\bin\keytool.exe -importcert -alias intermediateca -trustcacerts -file <IntermediateCA.cer> -keystore servletcontainer.jks -storetype jks -storepass
```

Import CA Reply

```bash
..\..\java\bin\keytool.exe -importcert -alias servlet-engine -trustcacerts -file <CertChainFromCA.p7b> -keystore servletcontainer.jks -storetype jks -storepass
```

Convert keystore to BCFKS format

Before running the following command, rename existing `servletcontainer.bckfs` to `servletcontainer.bckfs_prev`:

```bash
..\..\java\bin\keytool.exe -importkeystore -srckeystore servletcontainer.jks -srcstorepass changeit -destkeystore servletcontainer.bckfs -deststoretype bcfks -deststorepass changeit -providername BCIPS -providerpath ..\lib\bc-fips-*.jar -providerclass org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider
```

UNIX

Import Root CA and intermediate certificates

```bash
./../java/bin/keytool -importcert -alias rootca -trustcacerts -file <RootCA.cer> -keystore servletcontainer.bcfks -storetype bcfks -storepass changeit
```

```
./../java/bin/keytool -importcert -alias intermediateca -trustcacerts -file <IntermediateCA.cer> -keystore servletcontainer.jks -storetype jks -storepass
```

Import CA Reply
Deploying ZFE

../java/bin/keytool -importcert -alias servlet-engine -trustcacerts -file
<CertChainFromCA.p7b> -keystore servletcontainer.jks -storetype jks -storepass changeit

Convert keystore to BCFKS format

Before running the following command, copy the existing servletcontainer.bcfks to
servletcontainer.bcfks_prev:

../java/bin/keytool -importkeystore -srckeystore servletcontainer.jks -
srcstoretype jks -srcstorepass changeit -destkeystore servletcontainer.bcfks -
deststoretype bcfks -deststorepass changeit -providername BCFIPS -providerpath ../
lib/bc-fips-yyyy.jar -providerclass org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider

Securing the Session Server to MSS

To secure the session server to MSS, using the Administrative Console, you register the session server with its associated MSS. Once a certificate is trusted in MSS, secure connections are handled automatically.

1. As the administrator, log into MSS.
2. From the left panel, click Configure Settings > Trusted Certificates.
3. Select Management and Security Server. The list contains the certificates that are trusted by MSS.
4. Click Import to add the ZFE session server certificate to the list.

There is detailed help available in the Administrative Console documentation.

Securing the Session Server to the Host

Follow these steps to configure a TLS connection between the Reflection ZFE session server and a host that supports TLS:

1. Configure the keystore using the MSS Administrative Console
2. Configure the ZFE terminal session

How to configure the keystore in MSS

For a Reflection ZFE session to trust the TLS host it connects to, the public certificate of the host must be added to a trusted keystore using the Management and Security Server (MSS). The Reflection ZFE session retrieves this certificate the first time a session connects.

Open the MSS Administrative Console > Configure Settings > Trusted Certificates and choose Terminal Emulator Clients. You can access the documentation for the Administrative Console by clicking the Help icon in the upper right of the page.

When the certificate is successfully added to the MSS server's trusted keystore, you are returned to the list of certificates and you should see the new host.

How to configure a Reflection ZFE terminal session

Depending on your host type, you can configure a terminal session using different security protocols.
To configure a terminal session using TLS

To connect to the new trusted host using TLS, configure a Reflection ZFE terminal session as usual, and in the Settings dialog box, specify TLS as the security protocol. Make sure to specify the correct TLS port for the connection.

To configure a VT terminal session using Secure Shell (SSH)

Secure shell provides encrypted communications between the client and a VT host.

MSS has a known hosts list that contains the public keys of hosts that you can connect to using SSH. SSH connections can be made only to hosts already trusted by an administrator.

The first time an SSH connection is made from a Reflection ZFE session to a host, the known hosts file is downloaded from MSS to the Reflection ZFE session server.

When you attempt to create or edit a session using SSH in the session management panel, you will be notified if the key is not recognized as trusted and asked if you want to trust the key and continue.

- If you enter yes, the host will be trusted and added to the known host list, and you will be prompted for the SSH host password.
- If you do not answer yes, then the host will remain untrusted and the session will be disconnected.

You can also configure the SSH known hosts file manually by establishing an SSH connection from a Reflection ZFE session to the host, and adding the remote host’s key fingerprint to the known hosts list in MSS.

Configure known hosts file for SSH connections using MSS

To configure the known hosts file for SSH connections in MSS:

1. Connect to the system where MSS is installed and navigate to the server’s certificates folder: C:\ProgramData\Micro Focus\Mss\MssData\certificates (Windows) or /var/opt/microfocus/mss/Mssdata/certificates (UNIX).
2. Copy the public certificate file of the new SSH host into the MssData/certificates (Windows) or /etc/ssh/ssh_host_rsa_key.pub (UNIX) folder described above. Only ssh-rsa and ssh-dss are valid as public key types for MSS known_hosts entries.
   
   The host’s public key format can be OpenSSH, Base64-encode,.DER, or.PFX. The file should follow this format: hostname, IP-address key-type key. For example, a public key entry might look like this: alpsuse132, 10.117.16.232 ssh-rsa AAAAB3NzaC1yc2EAAAADAQABAAAf.......
4. Open the Administrative Console.
5. Click Configure Settings > Secure Shell.
6. Follow the directions in MSS to import a known host.

After the public key is imported into the known hosts file, you will return to the Secure Shell Known Hosts page and the new host will appear in the list.

Using ZFE with Docker

The Docker open platform has excellent documentation which you should read and understand.
Deploying ZFE

Why Docker?

Docker is a container-based platform that enables you to develop, deploy, and run applications within a container. Your application, plus any dependencies your application requires, such as binaries and libraries, and configuration information are held within the container. You can deploy multiple containers, all of which run in Docker and on top of the operating system.

Using Docker you can scale your applications vertically, meaning multiple instances of the session server can exist on one server and each instance will perform exactly as it did when you created and tested it.

What are the benefits?

Containerization delivers multiple benefits:

- **Performance**
  Virtual machines are an alternative to containers, however containers do not contain an operating system (unlike VMs). This means containers are faster to create, quicker to start, and have a much smaller footprint.

- **Agility**
  Because containers are more portable and have better performance, you can take advantage of more agile and responsive development practices.

- **Isolation**
  Docker containers are independent of one another. This is important because a Docker container containing one application, including the required versions of any supporting software, will not interfere with another container of the same application which requires different supporting software. You can have total confidence that at each stage of development and deployment the image you create will perform exactly as expected.

- **Scalability**
  Creating new containers is simple and quick. The Docker documentation has information on how to manage multiple containers.

Terminology

There are basic terms you need to be familiar with when working with Docker. For more information see the Docker Documentation site.

**Container**
A run-time instance of an image. A container is usually completely isolated from the host environment, only able to access host files and ports if it has been configured to do so. To run an image in a container you use the docker run command.

**Docker Hub**
A cloud-based community resource for working with Docker. Docker Hub is typically used for hosting images, but can be used for user authentication and automating the building of images. Anyone can publish images to Docker Hub.

**Docker Compose**
Compose is a tool that uses YAML files to configure your application services and then define and run multi-container Docker applications. To learn more about Compose visit the Docker Compose documentation.

**Dockerfile**
A text document containing the commands to build a Docker image. You can specify complex commands (such as specifying an existing image to use as a base) or simple ones (such as copying files from one directory to another). To build an image from a Dockerfile you use the docker build command.

**Image**

A standalone, executable package that runs in a container. A Docker image is a binary that includes everything needed to run a single Docker container, including its metadata. You can build your own images (using a Dockerfile) or use images that have been built by others and then made available in a registry (such as Docker Hub). To build an image from a Dockerfile you use the docker build command. To run an image in a container you use the docker run command.

**Getting Started with Docker and ZFE**

The ZFE install package contains an initial Dockerfile and accompanying application jar file to get you started using the session server in containers.

There are examples located in the `docker/samples` folder. See Docker Compose Examples for instructions.

There are four steps involved in creating the base image:

1. Install Docker and Docker Compose. Follow the instructions on the Docker web site.
   - Install Docker
   - Install Docker Compose
2. Extract the download package file and locate `Dockerfile` and `zfe.jar` in the Docker folder
3. Build the Docker image
4. Run the Docker image

**Build the session server Docker image**

Assuming you have followed steps one and two; installed Docker and Docker Compose and extracted and located Dockerfile and zfe.jar, the next step is to build the base Docker image of the session server.

1. Run this command from the folder containing the Dockerfile:

   ```bash
docker build -t zfe:<version> .
   ```

   Replace `<version>` with the version of the session server. If a version is not available, the default tag (-t) is `latest`.

2. Verify that the image was successfully created. Run:

   ```bash
docker images
   ```

   The output should contain information about the image you just built.

**Run the image**

Before you can run the session server image in a Docker container, you must set some environment variables.
You have two options that you can use:

- Use a bind mount
- Extend an existing Docker image

### Using a bind mount

A bind mount mounts a file or directory on the host machine into a container. The file or directory is referenced by its full or relative path on the host machine.

This bind mounts the keystore and truststore files on the host to the Docker container.

```bash
docker run --env SERVER_SSL_KEYSTORE=./etc/servletcontainer.bcfks \
--env SERVER_SSL_TRUSTSTORE=./etc/trustcerts.bcfks \
--env MANAGEMENT_SERVER_URL=https://localhost/mss \
--volume ~/certs/demo_keystore.bcfks:/opt/zfe/etc/servletcontainer.bcfks \
--volume ~/certs/demo_truststore.bcfks:/opt/zfe/etc/trustcerts.bcfks \
--expose 7070 \
--expose 7443 \
--publish 7070:7070 \
--publish 7443:7443 \
zfe
```

### Extending an existing Docker image

With this method you create a new Dockerfile to copy the files you need into the Docker image.

First, create a Dockerfile that will extend from the zfe Dockerfile FROM zfe:

```bash
COPY ./certs/demo_keystore.bcfks /opt/zfe/etc/servletcontainer.bcfks
COPY ./certs/demo_truststore.bcfks /opt/zfe/etc/trustcerts.bcfks
```

Next, build the extended Dockerfile, naming it demo.

```bash
docker build -t demo
```

Finally, run the demo image.

```bash
docker run --env SERVER_SSL_KEYSTORE=./etc/servletcontainer.bcfks \
--env SERVER_SSL_TRUSTSTORE=./etc/trustcerts.bcfks \
--env MANAGEMENT_SERVER_URL=https://localhost/mss \
--expose 7070 \
--expose 7443 \
--publish 7070:7070 \
--publish 7443:7443 \
demo
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SERVER_SSL_KEYSTORE</td>
<td>The path to the keystore file</td>
</tr>
<tr>
<td>SERVER_SSL_TRUSTSTORE</td>
<td>The path to the trust store file. It is required to import the MSS certificate into the trust store to communicate securely with MSS.</td>
</tr>
<tr>
<td>MANAGEMENT_SERVER_URL</td>
<td>The address of the MSS server</td>
</tr>
</tbody>
</table>

Variable Description

- **SERVER_SSL_KEYSTORE**: The path to the keystore file
- **SERVER_SSL_TRUSTSTORE**: The path to the trust store file. It is required to import the MSS certificate into the trust store to communicate securely with MSS.
- **MANAGEMENT_SERVER_URL**: The address of the MSS server
Examples

The examples, located in the `docker/samples` folder, walk you through four scenarios using Docker Compose. Compose is a tool that uses a YAML file to configure and run your applications with a single command.

Review the Docker documentation on Docker Compose before proceeding.

Prerequisites

To run the examples, you need:

- A running MSS server
- A keystore file to secure TLS connections to the session server
- A truststore file that has the MSS server certificate in place
- To build the session server Docker image

The examples include:

- A basic example providing a demo keystore and truststore files in which you can import a MSS server certificate.
- An hybrid example which assumes a local ZFE installation and mounts existing, on disk, keystore and truststore files to the Docker container.
- An extension example showing how to update, modify, and customize the ZFE web client
- A load balancer example illustrating how to balance between linked containers.

Basic

This basic example illustrates how to run the session server Docker image in Docker Compose. In this example you will import the MSS server certificate to enable secure communications with MSS.

By default, the session server listens on port 7070 (HTTP) and 7443 (HTTPS). If it is necessary to modify the ports, for example to 8443 and 8080, update the ports in the `docker-compose.yml` file:

```yaml
ports:
  - 8443:7443
  - 8080:7070
```

- To start the session server service:
  ```bash
docker-compose up
  ```
- To run the service in a daemon:
  ```bash
docker-compose up -d
  ```
- To look at running containers:
  ```bash
docker ps
  ```

Hybrid

In this example a local installation of ZFE, with existing keystore and truststore files on disk is present. These files will be mounted (copied) to the Docker container.

- To update the ports, modify `ZFE_PORT`, `ZFE_HTTP_PORT` in the `.env` file.
To update the MSS server address, modify `MSS_ADDRESS` in the `.env` file.

To start the session server service, copy `.env` and `docker-compose.yml` to `sessionserver/microservices/zfe/`, and run: `docker-compose up -d`.

**Extensions**

Using extensions and your own HTML, CSS, or JavaScript, you can update, modify, and customize the presentation of the web client from within the browser. See Extending the ZFE Web Client for more information.

This example sets `SPRING_PROFILES_ACTIVE` to `extensions-enabled` and maps the location of the extensions in `docker-compose.yml`.

To start the session server service:

```bash
docker-compose up -d
```

You could also choose to extend the base zfe Docker image and copy the extension files into the Docker container:

1. Create the Dockerfile that extends from the zfe Dockerfile.

   ```bash
   FROM zfe
   COPY ./certs/servletcontainer.bcfks /opt/zfe/etc/servletcontainer.bcfks
   COPY ./certs/trustcerts.bcfks /opt/zfe/etc/trustcerts.bcfks
   COPY ./extensions /opt/zfe/extensions/
   ```

2. Build the extended Dockerfile and name it `extensions`.

   ```bash
docker build -t extensions
   ```

3. Update `docker-compose.yml` to use the new extensions image

   ```yaml
   version: "3"
   services:
     zfe:
       image: extensions
       environment:
         - LOGGING_FILE=./logs/zfe.log
         - LOGGING_FILE_MAXSIZE=10MB
         - LOGGING_FILE_MAXHISTORY=10
         - SERVER_SSL_KEYSTORE=./etc/servletcontainer.bcfks
         - SERVER_SSL_TRUSTSTORE=./etc/trustcerts.bcfks
         - MANAGEMENT_SERVER_URL=https://${MSS_ADDRESS}/mss
         - METERING_ENABLED=false
         - METERING_HOST_REQUIRED=false
         - METERING_SERVER_URL=${MSS_ADDRESS}|https|meter
         - ID_MANAGER_SERVER_URL=https://${MSS_ADDRESS}/tidm
         - SPRING_PROFILES_ACTIVE=extensions-enabled
       ports:
         - ${ZFE_PORT}:7443
         - ${ZFE_HTTP_PORT}:7070
       expose:
         - 7443
         - 7070
   ```
Load Balance

HAProxy is a load balancer. Learn more about HAProxy on their web site.

This example, an haproxy service is included in the docker-compose.yml file. The example uses an HAProxy image to balance between linked containers. This example uses SSL Bridging to link the containers.

To provide secure communication between the clients and the load balancer, you must update the LOAD_BALANCER_CERT property in the .env file with the location of the load balancer certificate.

To help you test, you can generate a self-signed certificate:

1. Generate a unique private key (KEY):
   
   ```sh
   sudo openssl genrsa -out mydomain.key 2048
   ```

2. Generate a Certificate Signing Request (CSR):
   
   ```sh
   sudo openssl req -new -key mydomain.key -out mydomain.csr
   ```

3. Create a Self-Signed Certificate (CRT):
   
   ```sh
   openssl x509 -req -days 365 -in mydomain.csr -signkey mydomain.key -out mydomain.crt
   ```

4. Append KEY and CERT to loadbalancer.pem:
   
   ```sh
   sudo cat mydomain.key mydomain.crt > ./certs/loadbalancer.pem
   ```

To start the session server and haproxy services:

```sh
docker-compose up -d
```  
- or -

```sh
docker-compose up --scale zfe=n -d
```  
Where `n` is the number of session server instances.

You can change the number of session server instances after the services start:

```sh
docker-compose scale zfe=n
```
Managing ZFE

Creating and configuring sessions and making sure everything runs smoothly and securely means that your users will be successful. The following should help you administer and manage your Reflection ZFE sessions and host connections.

- Connecting to the Host
- Logging

Connecting to the Host

Reflection ZFE supports IBM 3270, 5250 and VT hosts as well as UTS, T27 and ALC host types.

To connect to the host:

1. From the Type drop down list, select the type of host you are connecting to.
2. Identify the host to which you want to connect. You can use a full host name or its IP address.
3. Type the number of the port you want to use.
4. Complete the information needed for the host connection.
5. Save your connection settings.

Your users gain access to the host through sessions that you create and configure. Sessions are created by an administrator in the MSS Administrative Console. When you launch a session from the Administrative Console, the web client Connection panel opens in a separate browser window. You configure connection options from this panel. Options vary depending on your host type.

- Providing access to the session
- Common connection settings
- 3270 and 5250 connection settings
- How to test Terminal ID Manager criteria
- VT connection settings
- UTS connection settings
- T27 connection settings
- ALC connection settings

Providing access to the session

Your users have access to their assigned sessions through a URL you provide (for example, https://<sessionserver>:7443/zfe). From this URL users select which session to open from the list of available sessions you have configured for them.
Your users can switch between sessions, open additional sessions and close sessions with which they are no longer working.

**NOTE:** A new session will not be launched if the specified session already exists when the user opens the link.

Alternatively, you can use *single session mode* and provide URLs to particular sessions that are launched using name and session parameters, (for example a direct link on a company portal page). To enable the launch of a single session use the query parameter `singleSession`. You can use this parameter on its own to just launch the Reflection ZFE web client in single session mode, for example, `http://<sessionserver>:7443/zfe/?singleSession`, or it can be used in conjunction with a named session parameter to launch a particular named session in single session mode: `http://<sessionserver>:7443/zfe/?singleSession&name=HumanResources`. The order of the parameters does not matter.

When your users access a single session, they cannot switch between open sessions and cannot open new sessions.

**Common connection settings**

These options are common to all supported host types.

- **Connect at startup**
  
  By default, sessions are configured to connect to the host automatically when you create or open a session. However, you can set up a session so that it doesn't automatically connect to the host. Choose No to manually connect to the host.

- **Reconnect when host terminates connection**
  
  When set to Yes, Reflection ZFE attempts to reconnect as soon as the host connection terminates.

- **Protocol**
  
  From the drop down list, select the protocol you want to use to communicate with the host. To establish a host connection, both the Reflection ZFE Web Client and the host computer must use the same network protocol. The available values are dependent on the host to which you are connecting. They are:
Table 4-1  Protocol Descriptions

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TN3270</td>
<td>TN3270 is a form of the Telnet protocol, which is a set of specifications for general communication between desktop and host systems. It uses TCP/IP as the transport between desktop computers and IBM mainframes.</td>
</tr>
<tr>
<td>TN3270E</td>
<td>TN3270E or Telnet Extended is for users of TCP/IP who connect to their IBM mainframe through a Telnet gateway that implements RFC 1647. The TN3270E protocol allows you to specify the connection device name (also known as LU name), and provides support for the ATTN key, the SYSREQ key, and SNA response handling. If you try to use Telnet Extended to connect to a gateway that doesn’t support this protocol, standard TN3270 will be used instead.</td>
</tr>
<tr>
<td>TN5250</td>
<td>TN5250 is a form of the Telnet protocol, which is a set of specifications for general communication between desktop and host systems. It uses TCP/IP as the transport between desktop computers and AS/400 computers.</td>
</tr>
<tr>
<td>Secure Shell (VT)</td>
<td>You can configure SSH connections when you need secure, encrypted communications between a trusted VT host and your computer over an insecure network. SSH connections ensure that both the client user and the host computer are authenticated; and that all data is encrypted.</td>
</tr>
</tbody>
</table>

There are two authentication options available:

- **Keyboard Interactive** - You can use this authentication method to implement different types of authentication mechanisms. Any currently supported authentication method that requires only the user's input can be performed with Keyboard Interactive.
- **Password** - This option prompts the client for a password to the host after a host connection is made. The password is sent to the host through the encrypted channel.

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Telnet (VT)</td>
<td>Telnet is a protocol in the TCP/IP suite of open protocols. As a character stream protocol, Telnet transmits user input from character mode applications over the network to the host one character at a time, where it is processed and echoed back over the network.</td>
</tr>
<tr>
<td>INT1 (UTS)</td>
<td>Provides access to Unisys 1100/1200 hosts using the TCP/IP network protocol.</td>
</tr>
<tr>
<td>TCPA (T27)</td>
<td>Use this protocol to connect to Unisys ClearPath NX/LX series or A Series hosts. TCPA Authentication is the process of verifying user login information. When properly configured, you can request a security credential from your application's credential server and send the credential back to the server. If the credential is valid, your application will be logged in; you do not have to enter a user ID or password. If the credential is not valid however, you will be prompted for a user ID and a password.</td>
</tr>
<tr>
<td>MATIP (ALC)</td>
<td>Mapping of Airline Traffic Over Internet Protocol (MATIP) uses TCP/IP for airline reservation, ticketing, and messaging traffic.</td>
</tr>
</tbody>
</table>

**Enable emulation tracing**

You can choose to generate host traces for a session. No is the default. Select Yes to create a new emulation host trace each time the session is launched. The trace file is stored in `<install directory>/sessionserver/logs/hosttraces/<date/yyyyymmdd>/<trace-file>`. Host trace files are created each time a session is launched.
3270 and 5250 connection settings

In addition to the common configuration settings, 3270 and 5250 host types require these specific settings.

- **Terminal model**
  
  Specify the terminal model (also known as a display station) you want Reflection ZFE to emulate. There are different terminal models available depending on the host type.

  If you choose **Custom Model**, you can set the number of columns and rows to customize the terminal model.

- **Terminal ID (3270 only)**
  
  When Reflection ZFE connects to a Telnet host, the Telnet protocol and the host negotiate a terminal ID to use during the initial Telnet connection. In general, this negotiation will result in the use of the correct terminal ID, and so you should leave this box empty.

- **TLS/SSL Security**
  
  SSL and TLS protocols allow a client and server to establish a secure, encrypted connection over a public network. When you connect using SSL/TLS, ZFE authenticates the server before opening a session, and all data passed between and the host is encrypted using the selected encryption level. The following options are available:

<table>
<thead>
<tr>
<th>Security options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>No secure connection is required.</td>
</tr>
<tr>
<td>TLS 1.2 - 1.0</td>
<td>Allow connection through TLS 1.2, TLS 1.1, TLS 1.0 depending on the capabilities of the host or server to which you are connecting. When <strong>Verify server identity</strong> is set to Yes, the client checks the server or host name against the name on the server certificate.</td>
</tr>
<tr>
<td>TLS 1.2</td>
<td>Select this value to connect using TLS. As part of the TLS protocol, the client checks the server or host name against the name on the server certificate when <strong>Verify server identity</strong> is set to Yes. This is highly recommended.</td>
</tr>
</tbody>
</table>

**NOTE:** See the section on **Securing connections** for information on adding trusted certificates, key stores, using SSH, and other advanced security information.

- **Verify server identity**
  
  When TLS/SSL security is set to TLS 1.2 or TLS 1.2-1.0, you have the option to verify the host name against the name on the server certificate. It is highly recommended that you enable host name verification for all sessions.

- **Device name**
  
  If you selected TN3270, TN3270E, or TN5250 as the protocol, specify the device name to use when the session connects to the host. The device name is also known as the host LU or pool.

  You can also choose to:

  - **Generate a unique device name.** An unique device name will be automatically generated.
- **Use Terminal ID Manager** which displays additional settings to complete.
- **Prompt User.** When you select this option the end user will be prompted for the device ID each time a connection is attempted.

If you do not specify a device name for the session, the host dynamically assigns one to the session. A device name that is set within a macro will override this setting.

If you selected **Terminal ID Manager** you can use it to provide IDs to client applications at runtime. You can use the Terminal ID Manager to manage pooled IDs for different host types. An ID is connection data that is unique for an individual host session. To use Terminal ID Manager, you must have a Terminal ID Manager server configured. See **Terminal ID Manager** in the Management and Security Server Installation Guide.

If you decide to use Terminal ID Manager and have configured the Terminal ID Manager server, then you can select from the options below to configure the criteria for acquiring an ID. All criteria must be met in order for an ID to be returned.

**NOTE:** Keep in mind that by specifying a criterion, you are indicating that the ID should be allocated only when an ID that has that specific value is found. The set of criteria selected here must be an exact match of the set of criteria specified on at least one Pool of IDs in Terminal ID Manager before the ID request can succeed.

<table>
<thead>
<tr>
<th>Criterion</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pool name</td>
<td>Include this attribute and enter the name of the pool to limit the ID search to a specified pool.</td>
</tr>
<tr>
<td>Client IP address</td>
<td>The IP address of the client machine will be included as part of the request for an ID.</td>
</tr>
<tr>
<td>Host address</td>
<td>The address of the host configured for this session will be included as part of the request for an ID.</td>
</tr>
<tr>
<td>Host port</td>
<td>The port for the host configured for this session will be included as part of the request for an ID.</td>
</tr>
<tr>
<td>Session name</td>
<td>When selected, requires that the ID is configured to be used by this session exclusively.</td>
</tr>
<tr>
<td>Session type</td>
<td>The session type (for example, IBM 3270, IBM 5250, UTS, ALC or T27) is always included as part of any request for an ID.</td>
</tr>
<tr>
<td>User name</td>
<td>Use this criterion to ensure that only IDs created for exclusive use by specific users will be allocated. The current user’s name, which must be found on an ID before it can be allocated, is the name of the user that the session is allocated to at runtime. To configure a session based on user names, a default placeholder user name is available: <code>tidm-setup</code>. For the administrator to configure sessions using <code>tidm-setup</code>, the Terminal ID Manager needs to have IDs provisioned for <code>tidm-setup</code>. You can override the default name with one of your own by modifying the Micro Focus/ReflectionZFE/sessionserver/conf/container.properties file as follows: <code>id.manager.user.name=custom-username</code> Where custom-username is replaced by the name you want to use.</td>
</tr>
<tr>
<td>Application name</td>
<td>The name of the host application will be used as part of the request for an ID. (UTS)</td>
</tr>
</tbody>
</table>

Managing ZFE  55
To determine the connection attempt behavior if Terminal ID Manager does not successfully allocate an ID to this session, use If ID is not allocated:

- **Fail connection attempt** - If selected, the session will not attempt to connect when an ID is not allocated.
- **Allow connection attempt** - If selected, the session will attempt to connect when an ID is not allocated. The attempt may be rejected by the host. There are some host types that permit a user to connect without an ID.

To confirm that Terminal ID Manager can provide an ID using the criterion and value selections you have made, click **Test**.

- **Send keep alive packets** - Use this setting to provide a constant check between your session and the host so that you become aware of connection problems as they occur. Choose from the following types of keep alive packets:

<table>
<thead>
<tr>
<th>This option</th>
<th>Does this....</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>The default. No packets are sent.</td>
</tr>
<tr>
<td>System</td>
<td>The TCP/IP stack keeps track of the host connection and sends keep alive packets infrequently. This option uses fewer system resources than the Send NOP Packets or Send Timing Mark Packets options.</td>
</tr>
<tr>
<td>Send NOP packets</td>
<td>Periodically a No Operation (NOP) command is sent to the host. The host is not required to respond to these commands, but the TCP/IP stack can detect if there is a problem delivering the packet.</td>
</tr>
<tr>
<td>Send timing mark packets</td>
<td>Periodically a Timing Mark Command is sent to the host to determine if the connection is still active. The host should respond to these commands. If a response is not received or there is an error sending the packet, the connection shuts down.</td>
</tr>
</tbody>
</table>

**Keep alive timeout (seconds)** - If you choose to use either the Send NOP packets or the Send timing mark packets option, select the interval between the keep alive requests set. The values range from 1 to 36000 seconds (1 hour); the default is 600 seconds.

### How to test Terminal ID Manager criteria

The Terminal ID Manager provides IDs to client applications at runtime. To confirm that Terminal ID Manager can provide an ID using the criteria and value selections you selected use this test option.

Criteria for the current session are specified on the Connection panel after selecting **Use Terminal ID Manager** from either the Device Name (3270, 5250 host types), the Terminal ID (UTS) field, or the Station ID (T27) field. By default, the selected criteria for the current session are displayed.

Click **Test** to confirm that Terminal ID Manager can provide an ID matching the configured criterion and value selections. The test returns the name of an available ID that satisfies the selected attribute values.

**Testing for other criteria and values**

You can also use this panel to test criteria different from those associated with the current session.

1. Select any of the session types from the Session type list, and select the criteria you want to test. You can test alternate values that you want to use in a sample Terminal ID Manager request.
2. Click **Test** to confirm that Terminal ID Manager can provide an ID matching the criterion and value selections. The test returns the name of an available ID that satisfies the selected values.
VT connection settings

In addition to the Common connection settings, VT hosts require additional settings. These settings vary depending on the protocol you are using; Telnet or SSH. The settings are applicable to both protocols unless noted.

Table 4-4  VT session configuration options

<table>
<thead>
<tr>
<th>VT Settings</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Terminal ID</td>
<td>This setting determines the response that Reflection ZFE sends to the host after a primary device attributes (DA) request. This response lets the host know what terminal functions it can perform. The Reflection ZFE response for each Terminal ID is exactly the same as the VT terminal's response; some applications may require a specific DA response. This terminal ID setting is independent of the Terminal type setting. The options are: VT220, VT420, VT100, DEC-VT100, and VT52.</td>
</tr>
<tr>
<td>Suppress banner messages (SSH)</td>
<td>When enabled, the SSH banner is not displayed. This option is useful when recording SSH login macros.</td>
</tr>
<tr>
<td>Local Echo (Telnet)</td>
<td>Automatic (default). How Reflection ZFE responds to remote echo from a Telnet host: Automatic attempts to negotiate remote echo, but does what the host commands. Yes means Reflection ZFE negotiates local echo with the host, but always echoes, while No means Reflection ZFE negotiates remote echo with the host, but does not echo.</td>
</tr>
<tr>
<td>Renegotiate Echo (Telnet)</td>
<td>No (default). When set to Yes, passwords are not displayed on the local screen, but all other typed text is visible. Reflection ZFE supports the Telnet Suppress Local Echo (SLE) option when connected to a host in half-duplex mode. This means that Reflection ZFE will suppress character echo to the host computer, and with SLE support Reflection ZFE can be instructed to suppress echo locally.</td>
</tr>
<tr>
<td>Set Host Window Size</td>
<td>Yes (default). This setting sends the number of rows and columns to the Telnet host whenever they change. This enables the Telnet host to properly control the cursor if the window size is changed.</td>
</tr>
<tr>
<td>Request Binary (Telnet)</td>
<td>No (default). Telnet defines a 7-bit data path between the host and the terminal. This type of data path is not compatible with certain national character sets. Fortunately, many hosts allow for 8-bit data without zeroing the 8th bit, which resolves this problem. In some cases, however, it may be necessary to force the host to use an 8-bit data path by selecting this check box.</td>
</tr>
<tr>
<td>Send LF after CR (Telnet)</td>
<td>No (default). A &quot;true&quot; Telnet host expects to see a CrNu (carriage return/null) character sequence to indicate the end of a line sent from a terminal. There are some hosts on the Internet that are not true Telnet hosts, and they expect to see a Lf (linefeed) character following the Cr at the end of a line. If you're connecting to this type of Telnet host, select Yes.</td>
</tr>
<tr>
<td>Ctrl-break sends (Telnet)</td>
<td>Choose what sequence Ctrl-break sends to the host when pressed. Options are: Telnet break sequence (the default), Interrupt process, or Nothing.</td>
</tr>
<tr>
<td>Host Character Set</td>
<td>The default value for the Host character set depends on the type of terminal you are emulating. This setting reflects the current terminal state of VT Host Character Set, which can be changed by the host. The associated default setting, saved with the model is DEC Supplemental.</td>
</tr>
<tr>
<td>Auto Answerback</td>
<td>No (default). This setting specifies whether the answerback message (set with the Answerback property) is automatically sent to the host after a communications line connection.</td>
</tr>
</tbody>
</table>
**VT Settings** | **Description**
---|---
Answerback String | This setting allows you to enter an answerback message if the host expects an answer in response to an ENQ character.

The answerback string supports characters with codes less than or equal to 0xFFFF via Unicode escape sequences. The escape sequence begins with \u followed by exactly four hexadecimal digits. You can embed Unicode escape sequences in any string. For example, this embedded \u0045 will be interpreted as this embedded E, since 45 is the hexadecimal code for the character E.

To pass Unicode escape sequences to the host, escape the sequence with a leading backslash. For example, to send the string literal \u001C to the host, map a key to \u001C. Reflection ZFE will convert this to the string \u001C when that key is pressed and send the 6 characters of the resulting string to the host.

---

**UTS connection settings**

In addition to the common connection settings, UTS hosts require these additional settings:

*Table 4-5  UTS INT1 session configuration options*

**UTS INT1 options** | **Description**
---|---
Application | The name of the host application or host operating mode to be accessed.

This is the word or phrase that the local machine sends to the host when you first establish communication with the host. If you were using a host terminal, this would be the $$OPEN name of the application. The application name is typically the same as the environment name. However, they can be different. For example, the environment name might be MAPPER, and the application might be UDSSRC. During a terminal emulation session, you would type $$OPEN MAPPER at the prompt, and INT1 would send UDSSRC to the host once the connection is established.

TSAP | The desired Transport Service Access Point (TSAP), up to 32 characters (such as TIPCSU for TIP connections, RSDCSU for Demand connections). A TSAP is required only if you are connecting to a Host LAN Controller (HLC) or to a Distributed Communications Processor (DCP) in IP router mode. If you're not sure which value to use, contact your host administrator.

Initial transaction | The character, word, or phrase that the local machine will send to the host when communication with the host is first established (up to 15 characters). This parameter is optional and is primarily used with TIP. For example, you might type ^ to run MAPPER. This parameter can also be used to transmit passwords.

Start transaction | When you configure an initial transaction, by default, the data is sent as soon as the session connection is established. You can decide when to send an initial transaction by using a particular string to trigger the initial transaction.

For example, to wait for a successful login before sending initial transaction data, type in a string to be used to identify a successful login.

You can use this setting in combination with **Send initial transaction**.
Managing ZFE

T27 connection settings

Along with the common connection settings, you can configure these additional T27 connection options:

Table 4-6  T27 Connection Settings

<table>
<thead>
<tr>
<th>T27 options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Terminal type</td>
<td>Select the type of terminal to emulate during the session. T27 emulation supports Unisys TD830, TD830 ASCII, TD830 INTL, and TD830 NDL terminal types</td>
</tr>
<tr>
<td>Request binary</td>
<td>You must enable the Request binary option when you require pass through printing. The default is No. TCPA defines a 7-bit data path between the host and the terminal emulator. This type of data path is not compatible with certain national character sets. However, many hosts allow for 8-bit data without zeroing the 8th bit, which resolves this problem. However, it may be necessary to force the host to use an 8-bit data path; you can do so by selecting this option.</td>
</tr>
<tr>
<td>Line width</td>
<td>Select the number of characters the host will send to the client. The default is 80 characters.</td>
</tr>
<tr>
<td>TLS/SSL security</td>
<td>See Table 4-2 TLS/SSL Descriptions for a description of the various options.</td>
</tr>
</tbody>
</table>

UTS INT1 options      Description

Send initial transaction You can determine when the initial transaction is sent:

- Immediately - Default.
- When start of entry (SOE) character is received - Useful when multi-line transactions must be completed before sending the string.
- After specified milliseconds

Terminal ID Choose whether to specify a terminal ID or use the Terminal ID Manager. To specify a terminal ID, type it in the Specify Terminal ID field.

If you choose Use Terminal ID Manager, you are prompted to select the Terminal ID attributes you want to use to obtain an ID. See Terminal ID Manager Attributes.

To test the attributes, click Test.

Specify Terminal ID The Terminal ID, a terminal identifier (typically up to 8 alphanumeric characters) to use for the communication session associated with this path. Also known as a TID or PID, each terminal ID should be unique to the host.
### ALC connection settings

In addition to the common connection settings, ALC hosts require these additional settings:

**Table 4-7  ALC Connection Settings**

<table>
<thead>
<tr>
<th>ALC options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TLS/SSL security</td>
<td>See Table 4-2 TLS/SSL Descriptions for a description of the various options.</td>
</tr>
<tr>
<td>Character encoding</td>
<td>Choose ASCII, EBCDIC, or IPARS (default) as the code set.</td>
</tr>
<tr>
<td>Configuration file</td>
<td>Enter the configuration (CNF) file that associates configuration information appropriate for a specific host type.</td>
</tr>
<tr>
<td>Terminal address</td>
<td>Select whether you want to specify the terminal address or use the Terminal ID Manager.</td>
</tr>
</tbody>
</table>

- **Terminal address -** Specify whether to use 2-byte or 4-byte addressing mode.

  Although a unique 5-byte address is required when you specify the terminal ID instead of using ID Manager, this option specifies how many bytes of the 5-byte terminal ID address are sent with each message for the purposes of multiplexing. If you specify 2-byte addressing mode, only the last 2 bytes of the ASCU (Agent Set Control Unit) cluster address (A1, A2) are sent. If you specify 4-byte addressing mode, the full ASCU cluster address (H1, H2, A1, A2) is sent.

  Specify the unique 5-byte terminal address for this session. The terminal address is made up of five 2-hex-digit values in this order: H1, H2, A1, A2, and TA (terminal address). This unique address is usually assigned by the network administrator.

- **Terminal ID Manager -** Provides IDs to client applications at runtime. If you choose this option, there are additional configuration options to complete. See Terminal ID Manager Criteria for descriptions of those options.
Logging

Locating log files

There are two log files available:

- ReflectionZFE/sessionserver/zfe.log - the log file for the ZFE session server application.
- ReflectionZFE/sessionserver/container.log - the log file for the container that hosts the ZFE application.

Configuring log rotation

You can configure log rotation by editing these values in ReflectionZFE\sessionserver\microservices\zfe\service.yml:

logging.file.max-size
logging.file.max-history

Setting logging levels

There are various types of logging levels you can use to produce different types of information. You can configure the logging levels supported by Log4J in ReflectionZFE\sessionserver\microservices\zfe\service.yml.

**NOTE:** Lines in service.yml must be indented using spaces.

Use the following format to set logging levels:

- name: logging.level.<logger>
  value: "<log level>"

Where <logger> is the name of the logger to adjust and <log level> is one of the following:

- Trace - designates finer-grained informational events than Debug
- Debug - designates fine-grained informational events that are most useful to debug an application.
- Info - designates informational messages that highlight the progress of the application at coarse-grained level.
- Warn - designates potentially harmful situations.
- Error - designates error events that might still allow the application to continue running.
- Fatal - designates very severe error events that will presumably lead the application to terminate.
There are multiple session and display options available so you can personalize your session and make sure you are working efficiently.

- Display Settings
- Map Keys
- Configure User Macros
- Transfer Files
- Specify Copy and Paste Options
- Working with Sessions
- Printing
- Customize Sessions
- Set User Preferences

**Display Settings**

Display settings vary depending on the host type and are specific to the session you are configuring.

- Color mapping
- Configure hotspots
- Configure screen dimensions for VT, UTS and T27 hosts
- Set cursor options
- Set font options
- Set VT scrollback buffer options
- Set keyboard options
- Terminal Settings
- Set other display options

**Color mapping**

You can customize the color of your screen and the appearance of different host attributes in the terminal window. For each item, you can select a color for the foreground and the background colors for all supported host connections. Colors are specified using the color grid or by entering the Hex code format.

There are many web sites that list available Hex colors, for an example see [w3schools.com HTML Color Picker](http://w3schools.com)

You may see different options depending on the type of host connection.
Options specific to UTS hosts:

- **Use color information from the host** - To use the colors specified here rather than any colors specified by the host, clear this option.

- **Enable blink** - To disable blinking, clear this option.

- **Select attribute to edit** - In UTS emulation, colors are set directly by the host. You can specify colors for text associated with specific screen display options. Including the following and available combinations:
  
  Plain, Underline (UND), Strikethru (STK), Left Column Separator (LCS), Control Page, and Status Line (OIA).

- **Video intensity** - The video intensities, Blink, Dim, Protected, and Reverse are combined with the attributes to create additional combinations. For example, you could map foreground or background colors to all cells with Dim + Blink + Underline or Reverse + Protected + Strikethru + Underline.

  When you select a video intensity (or combination of intensities), those intensities are combined with the value of the attribute drop down list to form a single color mapping.

Options specific to VT and T27 hosts:

- **Enable blink** - To disable blinking, clear this option.

- **Enable bold** - Displays text set with bold attributes as bold text in the terminal window. To display bold characters as plain text, clear this option.

- **Enable underline** - Displays text with underline.

- **Inverse video** (VT-only) - This option reverses the foreground and background colors when the VT host sends an inverse video escape sequence. If this option is not enabled, the inverse video sequences sent from the host are ignored.

To customize colors for all host types:

1. From the left navigation panel, click **Display**.

2. Under **Color Mappings**, click the background color field to open the color grid. From the color grid, select the color you want to use as the host background color. Alternatively, type the Hex color number for the color you want to use.

3. From the drop down list, select the default host color you want to change.

4. Open the color grid for the **Foreground** to choose a color to map the new color for the text or type the Hex code you want to use. Select **Background** to map the new color to the background field.

5. Click **Save** to close the Display panel and resume configuring your host connection.

**Restore defaults** clears any changes you made and resets the colors to the default host settings.

**Configure hotspots**

Hotspots are buttons that appear over common host commands in terminal sessions. When you use hotspots you can control the terminal session using a mouse or a finger-tap instead of the keyboard. The hotspot transmits a terminal key or command to the host. By default, hotspots are configured for the most common 3270, 5250, and VT commands.

Hotspots are enabled and visible by default, however you can disable hotspots for a particular session or choose to hide them.

- **Enable hotspots**
Choose **No** to disable hotspots for the session you are connecting to.

- **Show hotspots**
  Choose **No** to hide hotspots on the screen. Hotspots remain functional.

### Table 5-1  Hotspots for 3270 Hosts

<table>
<thead>
<tr>
<th>Hotspot</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PF1...PF24</td>
<td>Transmits a PF1...PF24 to the host</td>

### Configure screen dimensions for VT, UTS and T27 hosts

As an administrator you can select the number of columns and rows for VT, UTS and T27 sessions.

1. Open the Display panel.
2. Under **Dimensions**, specify the number of columns and rows you want each screen to possess. The default values are 80 columns by 24 rows.

   There are some host-specific settings available:
   - **Pages** - If you are connecting to a T27 host screen, you can set the number of pages to display. The default is 2.
   - **Clear on host change** - If you are connecting to a VT host screen, select this option to clear the terminal window and move the contents to the scrollback buffer when the column size changes.

3. Click **Save**.

### Set cursor options

Use the cursor options to configure the appearance and behavior of the cursor and ruler.
Set font options

Use these font options to make sure that your terminal characters display with your preferred font size and style.

<table>
<thead>
<tr>
<th>This option</th>
<th>Does this...</th>

</tr>
<tr>
<td></td>
<td>• <strong>Zero with a dot</strong></td>
</tr>
</tbody>
</table>

Set VT scrollback buffer options

The VT scrollback buffer contains the data that has scrolled off the display and is no longer accessible by the host computer. When a scrollback buffer exists, you can view it by using the vertical scroll bar.

The scrollback buffer is enabled by default. When enabled, the session maintains a buffer of lines that have scrolled off the terminal screen. This option is available to all users when they are granted permission to modify **Terminal Display Settings** by the administrator.
### This option | Does this...
---|---
Scrollbar row limit | Limits the number of rows held in the scrollback buffer. The default setting is 500 rows.
Save display before clearing | When selected (the default), the data on the terminal display moves into the scrollback buffer when you, or the host, clear the terminal display. If you prefer not to have the terminal display saved to the scrollback buffer, clear this option; when the terminal display is cleared, the data is discarded.
Save from scrolling regions | When top and bottom screen margins are set (for example, by a text editor such as EDT or TPU, or with the DECSTBM function) the area within the margins is called the scrolling region. When this option is cleared, scrolling text within this region isn’t saved to the scrollback buffer. Select this option to save information within scrolling regions to the scrollback buffer. **Note:** This can cause display memory to fill quickly.
Save before clearing from any row | This setting specifies whether data that has been cleared from a portion of the terminal window is saved in display memory.
Compress blank rows | Select this option to save room in display memory by compressing multiple blank rows into a single blank row.

### Set keyboard options

You can set the following keyboard options:

#### 3270 keyboard options

- **Type ahead**
  
  When this option is selected, Reflection ZFE buffers the characters that you type in the terminal window. Typeahead allows you to keep typing after you send data to the host. Without typeahead, characters you type are ignored until the host is ready for more data.

- **Word wrap**
  
  When this option is selected, word wrap functionality is enabled within a multi-line, unprotected field. In word wrap mode, some of the blank spaces between words are replaced by line breaks so that each line is visible in the terminal window and can be read without horizontal scrolling.

- **Attention key sends**
  
  Specifies what is sent when the ATTN key is pressed. The options are Telnet break, Abort output, and Interrupt process.

#### 5250 keyboard options

- **Type ahead**
  
  When this option is selected, Reflection ZFE buffers the characters that you type in the terminal window. Typeahead allows you to keep typing after you send data to the host. Without typeahead, characters you type are ignored until the host is ready for more data.

- **Error auto reset**
When selected, the next key pressed after a keyboard error clears the error, restores the previous error line data, and attempts to execute the keystroke as follows:

- If the cursor is in a valid input field and the key is a data key, the data is entered there if it is valid data for that field (for example, a numeric character in an input field that only accepts numbers).
- If the cursor is in a valid input field and the key is a function key, the key operation is executed.
- If the current cursor position is not in a valid input field and the key is a data key, the cursor is moved to the next valid input field and the data is entered there if it is valid data for that field.
- If the current cursor position is not in a valid input field and the key is a function key, the cursor is moved to the next valid input field and the key is ignored.
- If the current screen contains no valid input fields, you'll see an error message with each keystroke you press, and no keystrokes are executed.

When cleared, you must press Reset to clear the error message from the error line before you can resume data entry.

By default, this option is not selected.

- **Waive field checks for PF key**
  Select this option to allow PF keys to be sent to the host from restricted fields. This option is cleared by default.

## VT keyboard options

- **Backspace sends**
  Configures the function that the Backspace key sends. On the VT terminal keyboard the back arrow key (<x) is configurable: it can send either a delete (ASCII 127) or a backspace (ASCII 8) character.

- **Local echo (VT)**
  This option causes each character typed at the keyboard to be displayed on the screen. This option is cleared by default, because most hosts echo back received characters.

- **Cursor keys**
  Controls the characters that the four arrow keys (on both the numeric and editing keypad) transmit. This setting is typically set by the host. In general, you should keep this set to **Normal**.
  If the arrow keys aren't working properly, it may mean that this option remained incorrectly set to **Application** when a host program terminated abnormally. Changing this setting back to **Normal** should fix the problem with the arrow keys.

- **Keypad**
  Controls the characters that the numeric keypad keys transmit. This setting is typically set by the host. In general, you should keep this set to **Numeric**.
  If the number or PF keys aren't working properly, it may mean that this option was incorrectly left set to **Application** when a host program terminated abnormally. Changing this setting back to **Numeric** should fix the numeric keypad.
T27 keyboard options

- **Enable lower case** *(T27)*
  Enables lower case, as well as upper case letters to be displayed on the screen. Default. If this option is disabled only upper case letters will display.

Terminal Settings

Terminal settings vary depending on your host type.

3270 and 5250 terminal settings

- **Host character set**
  Select the 3270 or 5250 host character set you want to use. This setting chooses a conversion table to convert host characters (EBCDIC) into PC characters (ANSI). This setting should match the national character set used by your host system. If it doesn’t match, then some characters, such as accents, may not display correctly. See your host documentation for definitions of the characters in each set. The default value is US English (037).

- **Country extended graphics code** *(3270 only)*
  With this option selected (the default), additional characters are available in the configured National character set. See your host documentation for details.

VT terminal settings

- **Terminal type** *(VT)*
  Specifies which terminal should be emulated. These choices affect the codes generated by the numeric keypad, the interpretation of control functions, and the response to terminal identification requests.

- **Terminal ID** *(VT)*
  Specifies the response that Reflection ZFE sends to the host after a primary device attributes (DA) request. This response lets the host know what terminal functions it can perform. This setting is independent of the terminal type setting. When set to the default value of Reflection, Reflection ZFE responds to a primary DA request with the set of features it supports. If your host requires a more specific terminal ID, select another value from the list.

- **New line** *(VT)*
  Select this option to send both a carriage return and linefeed when you press Enter. When Reflection ZFE receives a linefeed, form feed, or vertical tab, it moves the cursor to the first column of the next line. When this option is cleared (default), the Enter key sends only a carriage return. A linefeed, form feed, or vertical tab received from the host moves the cursor down one line in the current column. If lines on the display keep getting overwritten (that is, the host is not sending a linefeed along with a carriage return), select this option. If the New line option is selected but the host does not expect to receive a linefeed with each carriage return, lines will be double-spaced on the display.
# T27 terminal settings

- **Host character set** (T27)

  Using this option you can specify host to screen translation. Select the language used to convert characters received from the host before they are displayed on the local machine. The default is No translation.

# Set other display options

Some display options are host-specific as noted below. When the host type is not indicated, the options apply to all supported host types.

<table>
<thead>
<tr>
<th>This option</th>
<th>Does this....</th>
</tr>
</thead>
<tbody>
<tr>
<td>Column separator style (5250)</td>
<td>Use this option to specify which character (if any) should be used to render column separators in 5250 terminal sessions. The options are:</td>
</tr>
<tr>
<td></td>
<td>- <strong>Dots</strong> - Dots are used to separate columns. The default.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Vertical bars</strong> - Vertical lines are used to separate columns.</td>
</tr>
<tr>
<td></td>
<td>- <strong>None</strong> - No characters are used to separate columns</td>
</tr>
<tr>
<td>Input field underlining (3270, 5250)</td>
<td>You can determine how the underlining of host input fields is handled:</td>
</tr>
<tr>
<td></td>
<td>- <strong>Host controls underlining</strong> (Default)</td>
</tr>
<tr>
<td></td>
<td>- <strong>Always underline input fields</strong></td>
</tr>
<tr>
<td></td>
<td>- <strong>Never underline input fields</strong></td>
</tr>
<tr>
<td>Status line (VT)</td>
<td>To enable a status line at the bottom of the display.</td>
</tr>
<tr>
<td></td>
<td>Choose:</td>
</tr>
<tr>
<td></td>
<td>- <strong>None</strong> to disable the status line. (Default)</td>
</tr>
<tr>
<td></td>
<td>- <strong>Indicator</strong> to display the page, cursor position, and printer status.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Host Writable</strong> to have the host application display information in the status line.</td>
</tr>
<tr>
<td>Preserve aspect ratio</td>
<td>Select this option to maintain the host screen aspect ratio regardless of the size of the browser window. Aspect ratio describes the proportional relationship between the width of an image and its height.</td>
</tr>
<tr>
<td>Display OIA (3270, 5250)</td>
<td>Select this option to display the operation and status messages in the Operator Information Area (OIA) at the bottom of the terminal window. By default, OIA display is enabled.</td>
</tr>
<tr>
<td>Display status line (ALC)</td>
<td>Turns on a status line at the bottom of the display.</td>
</tr>
<tr>
<td>Ignore mouse click on window activation</td>
<td>When a mouse click activates the terminal window, this option specifies whether actions such as updating the terminal cursor position, clearing a selection, or executing a hotspot are also performed. By default, these actions are not performed.</td>
</tr>
<tr>
<td>Auto wrap (VT)</td>
<td>When selected, characters automatically wrap at the right margin and continue on the next line. When cleared, characters do not wrap when they reach the right margin of the display. New characters overwrite the character at the right margin until a carriage return is entered.</td>
</tr>
</tbody>
</table>
Map Keys

You can create keyboard shortcuts that perform any assignable action during a session. The Key Mappings settings page provides a view of the default keyboard map for each host type and the mapped custom keys, indicated in boldface type, for that session.

Mapping keys as an administrator and as an end-user

There are a few differences in behavior between the administrator and the end-user when mapping keys.

* End users can only add or modify key mappings if they are granted permission by the administrator using the User Preference Rules panel.

* Any changes the administrator makes show up to the end user as indistinguishable from default host key mappings. Once granted permission, the person can modify, add or delete any mappings regardless of any administrator changes. However restoring key mappings only restores them back to the modified state created by the administrator for the current session.

Adding or modifying mapped keys

1. From the toolbar, click Settings.
2. From the left navigation pane, open the Key Mappings panel. The mapped keys for the host type you are connecting to are visible.
3. To add a new key mapping:
   * Click . You can choose to type the key sequence you want to use or use the keyboard by toggling between the two options.
   * From the Action drop down list, select the action you want to associate with the key selection. If you select Send text, enter the string you want sent to the host in the Value field. Likewise, if you select Run Macro, choose the macro you want triggered by the keyboard shortcut. You must create the macro before you can map it to the Run Macro action.
     The Send text action supports mapping characters with codes less than or equal to 0xFFFF via Unicode escape sequences. The escape sequence begins with \u followed by exactly four hexadecimal digits. You can embed Unicode escape sequences in any string. For example, this embedded \u0045 will be interpreted as this embedded E, since 45 is the hexadecimal code for the character E.
     To pass Unicode escape sequences to the host, escape the sequence with a leading backslash. For example, to send the string literal \u001C to the host, map a key to \u001C.
     Reflection ZFE will convert this to the string \u001C when that key is pressed and send the 6 characters of the resulting string to the host.
     The Disable action renders the key inoperable. When pressed the key will not initiate any action. This differs from the Unmap action which removes the ZFE key mapping but preserves a browser short-cut if it is defined.
   * Click the blue check mark to accept the mapping and add the key map to the session.
4. To modify an existing mapping:
   Select the row containing the key you want to modify.
Follow the steps for adding a new key mapping, clicking to save the new mapping. Alternatively, you can click away from the modified row and the change will be saved. All new and modified key maps are indicated in boldface type. You can restore the original key mapping at any time by clicking.

Filtering the list

The Filter field makes it easy to see just those mappings you are interested in. The filter is based on keywords and affects each column of the table. For example, if you enter Send text in the Filter field, only keys mapped to the Send text action are displayed.

Using the Show only modified mappings option lets you see only those mappings that have been previously modified.

Some things to remember:

- **Mapping right and left modifier keys to individual actions**
  
  You can map the right and left modifier keys to individual actions. However when they are combined with other keys, there is no differentiation between the right and left keys. For example, Left-Alt can be mapped to Action-A while Right-Alt is mapped to Action-B, but Left-Alt + H will be stored as Alt+H and both Left-Alt+H and Right-Alt+H will be associated with a single mapped action.

- **Key stroke combinations and copy/paste operations**
  
  Different key stroke combinations are also used for copy/paste operations. For example, on a VT host screen, Ctrl+Shift+A initiates a Select All action. See Copying and Pasting for a list of copy/paste key actions.

- **Keyboard shortcuts and browsers**
  
  Browsers use keyboard shortcuts to save both time and mouse clicks. When mapping keystrokes it is important to keep this in mind. Handy Keyboard Shortcuts gives a brief overview of the keyboard shortcuts used by different browsers. In most cases ZFE key mappings take precedence over browser key shortcuts. Occasionally, where this is not the behavior you want for a particular key combination, you can choose Unmap in the action list to unmap the shortcut. This lets the key event to pass through to the browser.

Host Keyboard Mapping

The following tables provide the default keys, key name, and key description for the different host keyboard mappings.

IBM 3270 Keyboard Mapping

### Configure User Macros

Use the Macro panel to select which macros to run and when to run them.

- **Run macro on startup** - Choose a macro to run automatically when the session is opened.
- **Run macro on connect** - Choose a macro to run automatically when the session connects to the host.
- **Run macro on disconnect** - Choose a macro to run automatically when the session disconnects from the host.

- Creating Macros
Transfer Files

Reflection ZFE supports two different file transfer protocols; IND$FILE for 3270 host transfers and File Transfer Protocol (FTP) which allows a local computer to act as an FTP client. Once connected, you can view files on the server and use the File Transfer Protocol (FTP) to transfer files between your local computer (or any networked drive) and the FTP server.

Batch file transfer is available for FTP transfers. Using this option you can download and upload multiple files in one operation.

Before you can transfer or send files, the administrator must enable the transfer and send options for the current session and make the necessary configurations. This is done on the File Transfer settings panel.

Depending on the host file system and transfer method you want to use, you will see different configuration options. Once configured, the file transfer dialog box is available from the tool bar.

- IND$FILE
- FTP
- Batch transfers

IND$FILE

IND$FILE is a file transfer program from IBM which you can use to transfer information between your computer and a 3270 host computer.

From the Host file system drop down list, select which IBM 3270 operating environment the host is running. Reflection ZFE supports TSO (Time Sharing Option), CMS (Conversational Monitor System) and CICS. The default selection is None.

There is support for ASCII or binary transfers and, if you connected to a TSO host, you can navigate directly to a particular TSO dataset.

General options for CICS, CMS, and TSO host file types

Automatically show host files - By default, the host file list contains all the host files that are available to transfer. To retrieve host files only when you request them, disable this option. On the Transfer dialog box, click Show host files to retrieve the host files.

Transfer options for CICS, CMS, and TSO host file types
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
| Transfer method        | **Binary**  Use for program files and other types of files that should not be translated, such as files that have already been formatted for a particular type of printer or files with application-specific formatting. Binary files contain non-printable characters; using this method, a file is not converted or translated during the transfer. 
**ASCII**  Use to transfer text files with no special formatting. ASCII files on the PC are translated to the EBCDIC character set on the host and host text files are converted from EBCDIC to ASCII when they are downloaded. |
| CR/LF processing       | If this option is selected, carriage return - line feed pairs will be stripped from files sent to the host and added to the end of each line on files received from the host.                                                                 |
| Startup command        | Specifies the host program used to initiate the file transfer. IND$File, the default, is appropriate for CMS and TSO hosts. For CICS hosts, IND$File may be appropriate, or you may need to specify your site’s CICS transaction (for example, CFTR). |
| Startup parameters     | Use this field for any parameters specific to the IND$File program on your host system. The contents of this field are appended to the end of the transfer command generated by Reflection ZFE. Reflection ZFE does not validate the parameters. |
| Max field size         | Select a field size to use with the Write Structured Field protocol. The default value is 4 kilobytes. Typically, the larger the buffer size, the faster the transfer. Most systems support 8K; if you choose a value that is too large for your host, it will disconnect your session when you first attempt to send a file big enough to fill the buffer. The person who installs the host communication software usually supplies this value. For example, IBM’s host TICP/IP product gets this value from the DATABUFFERPOOLSIZE parameter, which defaults to 8K buffers. See your system administrator if you don’t know what to enter here. |
| Lead key               | You can specify certain actions before transferring or listing files. Your choices are None, Auto Sense, and Clear. If set to None, LISTCAT is issued automatically. If set to Auto Sense, the current screen contents are examined to determine if a LISTCAT or TSO LISTCAT should be sent. If set to Clear, the Clear key is sent before issuing command. For TSO, Clear also means “TSO” will not be prepended to the request files command. |
| PC code page           | The character set to use when reading or writing local files during a file transfer. The value Default uses the code page corresponding to your operating systems locale. If you need a different character set to specify the PC code page, select it from the list. |
| Host code page         | The character set to use when translating EBCDIC characters while transferring files to or from the host. The default, Use NCS setting, uses the national character set specified on the Display panel under Terminal. If you need a different character set to specify the host code page, select it from the list. |
| Response timeout       | Specifies how many seconds Reflection ZFE should wait for a host response before timing out and returning an error. The default value is 60 seconds. |
| Startup timeout        | Specifies the number of seconds Reflection ZFE should wait for a host response when attempting to connect to a host. If the specified amount of time elapses with no response from the host, Reflection ZFE times out and returns an error. The default value is 25 seconds. |

<td>(allocation units)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
NOTE: When using CICS as the host system you must enter the names of the files you are transferring manually. A list of files to choose from is not available.

Transferring files

- Downloading files
- Uploading files
- Troubleshooting your file transfers

You must be connected and logged into the host to transfer files for the current 3270 session.

1. Verify that the host is in a ‘ready’ state to accept the IND$FILE command.

2. From the tool bar, click the IND$File icon.

3. The File Transfer dialog box displays, containing a list of host files and directories that are available to transfer. Directories and files are indicated by an icon when you select the file. For CICS hosts, type in the names of the files you want to transfer.

4. Select the transfer method. The options are:
   - Binary
     Use for program files and other types of files that should not be translated, such as files that have already been formatted for a particular type of printer or files with application-specific formatting. Binary files contain non-printable characters; using this method, a file is not converted or translated during the transfer.
   - ASCII
     Use to transfer text files with no special formatting. ASCII files on the PC are translated to the EBCDIC character set on the host and host text files are converted from EBCDIC to ASCII when they are downloaded.

5. If you are connected to a TSO host, click Level to type in the new dataset you want to view. Reflection ZFE updates the remote file list using the dataset level you specify.

NOTE: When specifying files using _Upload As_ or _Download_, a fully qualified data set name needs to be enclosed in single quotes. Data set names not enclosed in single quotes will, by default, be prefixed with a high level qualifier specified in the TSO PROFILE.

You can refresh the file list at any time by clicking the Refresh icon in the upper left corner of the File Transfer dialog box.

Downloading files

You can select files to download from the list of available files or use the Download button to identify a specific file using the host file name.

1. From the list, select the file to initiate the transfer by clicking on the name of the file in the list.

or
2 Click Download and enter the name of the host file you want to transfer. You can download from both TSO and CMS host types. However, TSO and CMS represent host files differently; this means the format of the file name you enter into the message prompt will vary.

- **TSO** - Wrap the name of the host path in single quotes to specify the complete dataset name. For example, "BVTST03.DATA.TXT". To specify a file location relative to the dataset level you set above, omit the single quotes. For example, DATA.TXT, which identifies the same dataset but relative to BVTST03.

- **CMS** - A typical CMS input would be BVTSTT01 DATA A1. Single quotes are not needed.

3 If necessary, you can cancel the transfer from the transfer progress panel.

### Uploading files

**NOTE:** IBM mainframe computer systems impose certain naming conventions for files. For detailed information on naming requirements, see the IBM documentation.

There are two methods for uploading files:

1. From the File Transfer dialog box, click **Upload**.

2. You can specify a different name for the uploaded file. Click **Upload as**, browse to the file you want to upload, and when prompted type the name you want to use. Remember that when connected to a TSO host, a fully qualified data set named needs to be enclosed in single quotes. See Step 5 under Transferring files.

Or:

1. Drag the file you want to upload from its location to the File Transfer dialog box.

2. Click **Refresh** to verify the file was successfully uploaded.

If you cancel the upload process before a file has been completely transferred, a partial file will be left behind on the host.

### Troubleshooting your file transfers

Occasionally you might encounter errors when attempting a file transfer. These errors may be mainframe issues or may be caused by browser security settings.

If a transfer completes but the file doesn’t contain the data expected, verify that the transfer method is properly set to either Binary or ASCII.

For host-specific errors, see IBM File Transfer Error Messages.

### FTP

With Reflection ZFE your local computer can act as an FTP client. Using the FTP client, you can connect to an FTP server running on another machine. Once connected, you can view files on the server and use FTP to transfer files between your local computer (or any networked drive) and the FTP server. Using FTP, a client can upload, download, delete, rename, move and copy files on a server, either singly or as a batch transfer, where you can build lists of files to be transferred as one operation.

**TIP:** If you plan on using a batch transfer, **Enable FTP** must first be selected and configured.

To configure FTP
Select Enable FTP and proceed with the configuration:

- **Protocol**
  Use FTP to start a standard FTP session. Use SFTP to start an SFTP session.
  You can set up an FTP client to use the SFTP protocol and perform all operations over an encrypted secure shell transport. Reflection ZFE uses user name and password to authenticate.

- **Host**
  Specify the host name or IP address of the FTP server to which you want to connect.

- **Port**
  The port of the FTP server specified.

- **If remote files exists when uploading file**
  Specify how you want to handle the transfer if a file with the same name already exists. You can select:

<table>
<thead>
<tr>
<th>This option</th>
<th>Does this...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Append</td>
<td>Append the file being sent to the existing file</td>
</tr>
<tr>
<td>Ask user (default)</td>
<td>Prompt for a decision on how to handle the duplicate file name</td>
</tr>
<tr>
<td>Cancel</td>
<td>Cancel the file transfer</td>
</tr>
<tr>
<td>Fail</td>
<td>Cancel the file transfer and receive a notification of failure</td>
</tr>
<tr>
<td>Overwrite</td>
<td>Overwrite the existing file on the remote machine</td>
</tr>
<tr>
<td>Skip</td>
<td>When multiple files are in a request, skip the file matching an existing file name, but proceed with the transfer for other files.</td>
</tr>
<tr>
<td>Unique</td>
<td>Create a new file with a unique file name</td>
</tr>
</tbody>
</table>

- **Initial remote directory**
  Specify the path to a home or default directory for the FTP site. When a connection to the FTP site is opened, the server working directory is set automatically to the specified home path. The files and folders in the server home directory appear in the FTP session window. If the initial remote directory is not found, a warning is reported and the connection continues.

- **Anonymous user**
  Select this option to log onto the specified FTP server as a guest, with the user name “Anonymous”. If the host you are connecting to does not support anonymous users, it may be necessary to supply your credentials.

- **Session timeout (seconds)**
  This value tells the FTP client the maximum number of seconds to wait for data packets being transferred to or from the host. If nothing is received within the period specified, a timeout error displays and the transfer terminates; in this case, try the operation again. If you receive repeated timeout errors, increase the timeout value. Entering 0 (zero) in this box prevents the FTP client from ever timing out when waiting for a response. For SFTP sessions, the default is 0 (zero).

- **Keep Alive time (seconds)**
  Select this option and enter a time in seconds if you want to continue your connection to the server beyond the server’s automatic timeout value for inactivity. Most servers have an idle time value that specifies how long a user’s FTP session can last when no activity is detected. When the user exceeds the time limit, the server connection is closed.
This setting allows you to direct the FTP client to send a NOOP command to the server at timed intervals to prevent the server from closing the connection due to inactivity. Be aware that by continuing your session you may prevent another user from making a connection to the FTP server.

- **Host encoding**

  Specifies the character set used by the host to display the names of files that are transferred. By default Reflection ZFE uses UTF-8 (Unicode). If you transfer files with the default setting and the file names are unrecognizable, change the Host encoding option to the character set used by the host. (This option does not affect the encoding for the contents of the files that are transferred; it applies to the file names only.)

### Transferring files

After the administrator configures a session to include FTP functionality, click the on the toolbar to open the FTP File Transfer window containing a list of host files that are available to transfer. Directories and files are indicated by an icon when you select the file.

1. Select the transfer method. The options are:
   - **Binary**
     Use for program files and other types of files that should not be translated, such as files that have already been formatted for a particular type of printer or files with application-specific formatting. Binary files contain non-printable characters; using this method, a file is not converted or translated during the transfer.
   - **ASCII**
     Use to transfer text files with no special formatting. ASCII files on the PC are translated to the EBCDIC character set on the host and host text files are converted from EBCDIC to ASCII when they are downloaded.

2. You can rename, delete, or download a file from the list of files.

3. Refresh the file list at any time by clicking the Refresh icon in the upper left corner of the File Transfer dialog box.

### Downloading files

1. From the list, select the file to initiate the transfer.
2. If necessary, you can cancel the transfer from the transfer progress panel.
Uploading files

There are two methods for uploading files:

1. From the File Transfer dialog box, click **Upload**.
2. Choose the file you want to upload from the Browse window.

Or:

1. Drag the file you want to upload from its location to the File Transfer dialog box.
2. Click **Refresh** to verify the file was successfully uploaded.

Click **New Directory** to create a new directory on the remote server. You are prompted to enter the new directory name.

Batch transfers

**NOTE:** You must first enable FTP on the File Transfer settings panel FTP tab before you can configure batch transfers.

To transfer multiple files in one operation, use the **Batch** option.

1. From the **Settings > File Transfer > FTP** panel, check **Enable FTP**.
2. Click **FTP** to open the **Batch** file transfer panel.
3. Select **Cancel batch when single failure occurs** to stop the transfer if a file fails to transfer.
4. Click **+** to create the list of files you want to transfer.
   a. Name the list. To aid in building similar lists, you can copy an existing list, rename it, and then add or delete files as needed using the options available when the original list is highlighted.
   b. From the right panel, click **+** to open the **Add transfer request** dialog box.
5. On the **Add transfer request** panel, begin building the list:
TIP: Administrators grant permission to transfer files using the User Preference Rules option from the Settings panel.

Click on the tool bar to open the list that contains the files you want to transfer.

1. Due to browser requirements, you need to specify the location of all files that you want to upload. Locate files as needed using the Search icon. Those files are easily identified with a yellow icon as such:

<table>
<thead>
<tr>
<th>Local file name</th>
<th>Transfer</th>
<th>Remote file path</th>
</tr>
</thead>
<tbody>
<tr>
<td>✅  ▲ Locate &quot;acd.jpg&quot;</td>
<td>▲ Upload</td>
<td>aed.jpg</td>
</tr>
<tr>
<td>✅  ▲ Locate &quot;ascii.txt&quot;</td>
<td>▲ Upload</td>
<td>ascii.txt</td>
</tr>
</tbody>
</table>
2. Files in the batch list are selected by default. To edit the file prior to transfer, you can eliminate files from the transfer operation by clearing their respective check boxes, or by selecting All from the drop down menu. You can also filter the list of transferable files based on their download or upload status.

3. Click Start to initiate the transfer.

Specify Copy and Paste Options

You can specify different options to use for copy and paste operations.

Copy options

Select text by dragging over it with the mouse. By default, different host types use different selection modes when copying text; IBM 3270, 5250 and UTS hosts use a block selection mode, while VT hosts use a linear selection mode. To toggle between block and linear selection modes, press and hold down the Alt key, then select the text.

- **Copy input fields only** - Select this option to only copy data from input fields. Data from protected fields is replaced with spaces when placed on the clipboard.
- **Use entire display when there is no selection** - This option applies the Copy command to the entire terminal display when nothing is selected.

Paste options

Click Paste to paste the contents of the clipboard at the cursor location.

- **Restore starting cursor position after paste** - By default, the host cursor is positioned at the end of the data following a paste operation. Select this option to restore the host cursor to its starting position after the paste operation is complete.
- **Mask protected fields** - Specifies how pasted text is mapped onto the screen:
  --If unselected (the default), the text is interpreted as a linear stream that can contain new lines and delimiters, and is pasted accordingly.
  --If selected, the text is interpreted as a host screen data and overlaid onto the current screen starting at the current cursor position. Where the current screen contains an unprotected field, the source text is pasted; where the current screen contains a protected field, the source text is skipped.

Key combinations

There are certain key combinations that map to different copy/paste actions.

<table>
<thead>
<tr>
<th>Key Combination</th>
<th>Host type</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ctrl + A</td>
<td>UTS, 3270, 5250</td>
<td>Select all</td>
</tr>
<tr>
<td>Shift + Arrow key</td>
<td>UTS, 3270, 5250, VT</td>
<td>Change the extent of the current selection</td>
</tr>
<tr>
<td>Ctrl + C</td>
<td>UTS, 3270, 5250</td>
<td>Copy</td>
</tr>
<tr>
<td>Ctrl + V</td>
<td>UTS, 3270, 5250</td>
<td>Paste</td>
</tr>
<tr>
<td>Ctrl + Shift + A</td>
<td>VT</td>
<td>Select all</td>
</tr>
<tr>
<td>Ctrl + Shift + C</td>
<td>VT</td>
<td>Copy</td>
</tr>
<tr>
<td>Ctrl + Shift + V</td>
<td>VT</td>
<td>Paste</td>
</tr>
</tbody>
</table>
Working with Sessions

All the sessions you have access to are available in the Available Sessions list. Sessions are initially created and configured by your system administrator and accessed through a distributed URL (for example, https://<sessionserver>:7443/zfe).

- Using Quick Keys
- Copying and Pasting
- Creating Macros
- Logging Out

To open a session

1. Select the session and click to open.
2. Interact with your host application using the open session.
3. You can create multiple instances of a configured session.

You can have multiple sessions open at a time and easily switch between them using the tabs arranged across the top of the screen. The current session is always the left-most tab and is indicated by a white background and bold text. Each session remains active for 30 minutes.

Use the toolbar to access the various options available to you as you interact with the session. You can disconnect from a session, close the session, turn on Quick Keys, and access other settings. Some options may be only available once your administrator has granted permission.

Using Quick Keys

The Quick Key terminal keyboard provides a graphical representation of the keys on a host keyboard and gives you quick access to terminal keys. Click a terminal key on the Quick Key keyboard to send the key to the host. Tool tips, which are available by hovering over a key, provide a description of the mapping.

Quick keys are available for each supported host type and are accessed by clicking the tool bar icon.

Copying and Pasting

**NOTE:** Each browser handles copy and paste functions differently and in some cases will not support the use of copy and paste buttons. It is highly recommended that you use keyboard commands for those functions. Although keyboard commands vary depending on your operating system, in Windows they are: **CTRL+C** to copy and **CTRL+V** to paste.

To copy from the terminal

1. Highlight the area on the terminal screen that you want to copy.
2. Click **Copy** from the toolbar or use the keyboard command, **CTRL+C**.
To paste into the terminal screen

1 Position the cursor where you want to paste content.
2 Use the keyboard command, CTRL+V, or click Paste from the toolbar. If your browser does not support pasting from the toolbar, you will be prompted to use the keyboard command.

Creating Macros

A macro is a series of keyboard actions that you record and then run. You can use these JavaScript macro programs to automate user interactions with the terminal. You can access and run macros from all supported devices.

Reflection ZFE records and saves advanced macros as JavaScript, making it easy to edit and enhance your recorded macros. You can record macros to playback later, run macros at startup or when the session connects or disconnects from the host. You can also write macros from scratch to perform complex tasks that the recorder cannot capture.

Macros are made available to users in two ways; created by an administrator or recorded by users for their own private use. All advanced macros are associated with a session and they all accomplish the same goal, automating host interaction. The only difference between the two flavors is simply who can access them and who manages their creation and availability:

- **Macros created by administrators**
  Administrators create macros when they create the session. They are specific to a session and are available to all users who have access to the session from the Macro icon on the toolbar. Administrators can designate macros to run at startup or when the session connects or disconnects from the host.

- **Macros created by users**
  End-user macros are created by individuals for sessions they are authorized to access. The administrator grants permission to create macros by setting a User Preference Rule. Users can access the session under their own credentials or in a Guest role. Macros that Guest users create are available to all Guest users. Users who are logged in using their own credentials can only see macros that they have created.

Advanced macros are listed in alphabetical order in the drop down list available from the toolbar. Macros created by the end-user are listed first and followed by an indicator of three vertical grey dots, which when selected, displays the Edit and Delete options. Macros created by the administrator are listed without the indicator as those macros cannot be modified by the end-user.

- To record a macro
- To edit a macro
- To run a macro
- To stop a macro
- To delete a macro
- To view macros
- To debug a macro
- Using the Macro API
To record a macro

1. Click the Macro icon on the toolbar, and then click **Record New Macro**.

![Macros]

2. Navigate the host application to record the series of steps you want included in the macro.

3. Click on the toolbar to stop recording. The red dot pulses to indicate the recording is in process.

4. When prompted, type a name for the macro.

To edit a macro

You can edit macros that you have recorded. These macros are listed under **My Macros**.

To edit an existing macro:

1. From the Macro drop down list, select the macro you want to edit.

   ![My Macro]

2. Click the three vertical dots to expand the field.

3. Click to open the Macro Editor.

   The Macro Editor opens in the left panel.

   The Macro Editor opens in the left panel.

4. Use JavaScript to make whatever changes are necessary. You can run and save the modified macro using the toolbar icons in the upper panel of the editor.

To run a macro

To run a macro, choose the macro from the drop down list and click .

You can also map keys that will automatically trigger an already recorded macro. In the Key Map settings dialog box, choose Run Macro from the Action drop down list. Choose a macro to associate with the key mapping from the Value list.

To stop a macro

You can stop a macro before it completes from either the Macro Editor or the toolbar. Click to stop the macro. To rerun the macro, navigate back to the macro starting screen.

To delete a macro

1. From the Macro drop down list, select the macro you want to delete.
2. Expand the field, by clicking the three vertical dot icon.

3. Click Delete.

To view macros

The Macro drop down list is available from the toolbar to all users who have permission to record macros or are accessing a session where macros have been pre-recorded by the administrator for use with that session.

Macros are listed under either MY MACROS or MACROS depending on how they were recorded.

All users, whether they are logged in using their credentials or as Guest, can see the macros associated with the session. Macros listed under the MY MACROS heading are listed in alphabetical order by name and are visible to those users that recorded them. Macros recorded by the administrator and attached to a session are listed alphabetically under MACROS.

To debug a macro

Since macros are written in JavaScript and executed in the browser, the best way to debug and troubleshoot them is by using your web browser’s built-in tools. Modern browsers come with a very capable set of tools for debugging JavaScript code. You can place breakpoints, step through code, and output debug information.

**TIP:** JavaScript is case sensitive. Keep that in mind when editing JavaScript code.

To debug a macro:

1. Open the macro for editing. See To edit a macro for instructions.
2. Open your browser's development tools.

<table>
<thead>
<tr>
<th>Browser</th>
<th>Open debugger</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mozilla Firefox 40.0.3</td>
<td>• From the toolbar, open the Menu, and choose Developer.</td>
</tr>
<tr>
<td></td>
<td>• From the Web Developer menu, choose Debugger. The debugger opens in a lower panel.</td>
</tr>
<tr>
<td>Google Chrome 45.0</td>
<td>• From the toolbar, open the Menu, and choose More tools.</td>
</tr>
<tr>
<td></td>
<td>• Choose Developer Tools to open the Debugger.</td>
</tr>
<tr>
<td>Microsoft Internet Explorer 11</td>
<td>• From the toolbar, open Settings, and choose F12 Developer Tools.</td>
</tr>
<tr>
<td></td>
<td>• Open the Debugger tab.</td>
</tr>
</tbody>
</table>
These instructions are for supported browsers and are dependent on the versions used.

3. Use one of these tools in your macro code, and run the code.

- **debugger**

  The most thorough approach to debugging is to use the ‘debugger;’ statement. When you insert these statements into your macro code then run it, with the browser’s development tools open, the execution will stop on those lines. You can step through your macro, view the value of local variables and whatever else you need to check.

  You are encouraged to place multiple debugger; statements in your code to help get to the correct line. The asynchronous nature of JavaScript can make stepping through code challenging. This can be offset by using multiple, carefully placed debugger; statements.

  **Example 5-1  Debugger**

  ```javascript
  var hostCommand = menuSelection + '[enter]';
  debugger; // <- Browser's debugger will stop here
  ps.sendKeys(hostCommand);
  ```

- **console.log(), alert()**

  These two functions are commonly used for debugging JavaScript. While not as flexible as the debugger statement they provide a quick way to output debug information. These functions output the information to the JavaScript “Console” tab in the browser’s developer tools.

  **Example 5-2  console.log(), alert()**

  ```javascript
  var hostCommand = menuSelection + '[enter]';
  console.log('Command:' + hostCommand); // <- Will output the string to "Console" tab
  alert('Command:' + hostCommand); // Will pop up a small window containing the data
  ps.sendKeys(hostCommand);
  ```

- **ui.message()**

  The Reflection ZFE Macro API provides an ui.message() function that is very similar to JavaScript's alert() function. You can also use ui.message() to output debug information.

  **Example 5-3  ui.message()**

  ```javascript
  var hostCommand = menuSelection + '[enter]';
  ui.message('Command:' + hostCommand); // <- Will pop up a ZFE message window
  ps.sendKeys(hostCommand);
  ```

**Notes to keep in mind when debugging macros**

- Stepping and “yields”
While the yield statements in macros make them easier to understand, they can make the code more challenging to step through with the debugger. Consider either using multiple debugger statements or carefully placed debugger statements of `console.log()` calls to output the right debug information.

- Internet Explorer

Debugging in Internet Explorer involves transformed code and may be more difficult than on other browsers.

**Using the Macro API**

In Reflection ZFE macros are recorded and written using JavaScript. JavaScript is a popular and prevalent programming language. There are a wide variety of learning resources and tools available to you.

The Reflection ZFE Macro API consists of a set of objects which you can use to interact with the host, wait for screen states, and interact with the user.

**About promises and yields**

Because JavaScript is single threaded and uses 'callback functions' and 'promises' to help manage the flow of execution through code, often code can be difficult to follow. Reflection ZFE combines the concept of 'promises' with the 'yield' keyword so macro code can be organized in a more linear fashion.

- **Promises**

  Promises are patterns to help simplify functions that return their result asynchronously, at some point in the future. All 'wait' and 'ui' functions in the Reflection ZFE Macro API return promise objects.

- **Yield**

  Reflection ZFE macros use the yield keyword to block the execution of the macro until a promise is resolved, or done. So putting yield in front of any 'wait' or 'ui' function makes the macro execution pause until that function has finished executing. You can place the yield keyword in front of any function that returns a promise, even your own custom functions.

**NOTE:** The ability to make macro execution block by combining yield with promises is enabled by the `createMacro()` function.

**Errors**

Errors are handled in macros using a try / catch statement. Some API functions may throw errors if, for example, conditions can’t be met or a timeout occurs. The thrown error is ‘caught’ in the catch statement. You can wrap smaller blocks of code in a try / catch statement to handle errors at a more granular level. Macro developers can also throw errors with `throw new Error('Helpful error message');`

**Related Topics**

- Macro API Objects
- Sample Macros
Macro API Objects

You can create macros using the Macro API. By default for use in macros, there are four primary objects available:

- **Session**
  Session is the main entry point for access to the host. You use the Session object to connect, disconnect and provide access to the PresentationSpace object.

- **PresentationSpace**
  The PresentationSpace object represents the screen and provides many common capabilities such as getting and setting the cursor location, sending data to the host and reading from the screen. It is obtained by calling `session.getPresentationSpace()`.

- **Wait**
  Provides a simple way to wait for various host states to occur before continuing to send more data or read from the screen. For example, you can wait for the cursor to be located at a certain position, text to be present in a position on the screen or simply wait for a fixed amount of time. All 'Wait' function calls require the `yield` keyword, which is explained below.

- **User Interface**
  The UI object is made automatically available in your macro as the "ui" variable. It provides basic user interface capabilities. You can use this object to display data to the user or prompt them for information. All 'UI' function calls require the `yield` keyword.

Other available objects:

- **Attribute**
- **AttributeSet**
- **AutoSignon**
- **Color**
- **ControlKey**
- **DataCell**
- **Dimension**
- **Field**
- **FieldList**
- **FileTransferFactory**
- **FileTransfer**
- **File Transfer Options**
- **HostFile**
- **Host File Type**
- **OIA**
- **OIAStatus**
- **Position**
- **SessionType**
- **StatusSet**
**Attribute**

Use the Attribute, along with the AttributeSet, to decode the formatting information present on the data cell.

**Table 5-11 Attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROTECTED</td>
<td>Indicates a protected data cell.</td>
</tr>
<tr>
<td>MODIFIED</td>
<td>Indicates a modified data cell.</td>
</tr>
<tr>
<td>NUMERIC_ONLY</td>
<td>Indicates the beginning of a numeric only data cell.</td>
</tr>
<tr>
<td>ALPHA_NUMERIC</td>
<td>Indicates an alpha numeric data cell.</td>
</tr>
<tr>
<td>HIGH_INTENSITY</td>
<td>Indicates whether the data cell contains high intensity text.</td>
</tr>
<tr>
<td>HIDDEN</td>
<td>Indicates whether the data cell contains hidden text</td>
</tr>
<tr>
<td>PEN_DETECTABLE</td>
<td>Indicates whether the data cell is pen detectable</td>
</tr>
<tr>
<td>ALPHA_ONLY</td>
<td>Indicates an alpha only data cell.</td>
</tr>
<tr>
<td>NUMERIC_SHIFT</td>
<td>Indicates the beginning of a numeric shift field</td>
</tr>
<tr>
<td>NUMERIC_SPECIAL</td>
<td>Indicates the data cell marks the beginning of a numeric special field</td>
</tr>
<tr>
<td>KATAKANA_SHIFT</td>
<td>Indicates a section of Katakana text.</td>
</tr>
<tr>
<td>MAGNETIC_STRIPE</td>
<td>Indicates the data cell marks the beginning of a magnetic strip field.</td>
</tr>
<tr>
<td>SIGNED_NUMERIC_ONLY</td>
<td>Indicates the data cell is a signed numeric field.</td>
</tr>
<tr>
<td>TRANSMIT_ONLY</td>
<td>Indicates the data cell is a transmit only field</td>
</tr>
<tr>
<td>FIELD_END_MARKER</td>
<td>Indicates the data cell marks the end of a modified field.</td>
</tr>
<tr>
<td>FIELD_START_MARKER</td>
<td>Indicates the data cell marks the start of a modified field.</td>
</tr>
<tr>
<td>SPECIAL_EMPHASIS_PROTECTED</td>
<td>Indicates a special emphasis protected field.</td>
</tr>
<tr>
<td>TAB_STOP</td>
<td>Indicates that the data cell contains a tab stop.</td>
</tr>
<tr>
<td>REVERSE</td>
<td>Indicates the data cell displays in reverse video mode.</td>
</tr>
<tr>
<td>BLINKING</td>
<td>Indicates the data cell contains blinking text</td>
</tr>
<tr>
<td>RIGHT_JUSTIFIED</td>
<td>Indicates the data cell marks the beginning of a right justified field.</td>
</tr>
<tr>
<td>LEFT_JUSTIFIED</td>
<td>Indicates the data cell marks the beginning of a left justified field.</td>
</tr>
<tr>
<td>LOW_INTENSITY</td>
<td>Indicates the data cell contains low intensity text</td>
</tr>
<tr>
<td>UNDERLINE</td>
<td>Indicates the data cell contains underlined text.</td>
</tr>
<tr>
<td>DOUBLE_BYTE</td>
<td>Indicates the data cell contains double byte text.</td>
</tr>
<tr>
<td>COLUMN_SEPARATOR</td>
<td>Indicates the data cell contains a column separator.</td>
</tr>
<tr>
<td>BOLD</td>
<td>Indicates the data cell contains bold text.</td>
</tr>
<tr>
<td>DOUBLE_WIDTH</td>
<td>Indicates the data cell marks a double width field.</td>
</tr>
<tr>
<td>DOUBLE_HEIGHT_TOP</td>
<td>Indicates a double height top data cell.</td>
</tr>
</tbody>
</table>
The AttributeSet object allows the user to decode the attributes that are present on the data cell. The AttributeSet object returns values defined in the Attribute object and when used together, you can get formatting information from the data cell.

### Table 5-12  AttributeSet

</tbody>
</table>

**METHODS**

**contains(attribute)**

Determines if the set contains the specified Attribute.

**Parameters**

{Number} attribute to check

**Returns**

{Boolean} True if the attribute is in the set.

**isEmpty()**

Determines if the attribute set is empty.

**Returns**

{Boolean} True if the set is empty.

**size()**

Indicates the number of attributes in a set.

**Returns**

{Number} The attribute count.

**toArray()**

Converts the internal attribute set to an array.

**Returns**

{Number[]} Array of values of attributes in the set.

**toString()**

Converts the internal attribute set to a string.

**Returns**

{String} Space-delimited names of attributes in the set.
METHODS

forEach(callback, thisArg)

Function to iterate over each element in the attribute set.

Parameters

{forEachCallback} Callback to perform the specific operation. Called with the name of each attribute in the set.

{Object} thisArg optional pointer to a context object.

forEachCallback(string, object)

A user provided callback function where you provide the behavior, to be used as the callback parameter to forEach.

Parameters

{String} String name of an attribute in the attribute set.

{Object} thisArg optional pointer to a context object.

Color

Color constants to use for the DataCell object foreground and background colors.

Table 5-13  Color constants

**ControlKey**

The ControlKey object defines constants for sending cursor control keys and host commands using the sendKeys method. Constants are available for these host types:

- IBM 3270
- IBM 5250
- VT
- UTS

**IBM 3270**

<td>Toggles insert/overwrite mode.</td>
</tr>
<tr>
<td>INSERT_IN_LINE</td>
<td>Inserts space at cursor position and shifts the remaining characters on the line to the right. The character in the far right column on the line is discarded.</td>
</tr>
<tr>
<td>INSERT_IN_PAGE</td>
<td>Inserts space at cursor position and shifts the remaining characters on the page to the right. The character in the far right column on each line is discarded.</td>
</tr>
<tr>
<td>INSERT_LINE</td>
<td>Inserts a new line at the cursor row and shifts the remaining lines down. The last row on the page is discarded.</td>
</tr>
<tr>
<td>LEFT_ARROW</td>
<td>Moves the cursor one position to the left wrapping if necessary.</td>
</tr>
<tr>
<td>LOCATE_FCC</td>
<td>Finds the next field control character on the screen.</td>
</tr>
<tr>
<td>MSG_WAIT</td>
<td>Retrieves messages queued to the terminal.</td>
</tr>
<tr>
<td>RETURN</td>
<td>Carriage return</td>
</tr>
<tr>
<td>RIGHT_ARROW</td>
<td>Moves the cursor one position to the right, wrapping if necessary.</td>
</tr>
<tr>
<td>SOE</td>
<td>Inserts the Start of Entry character</td>
</tr>
<tr>
<td>START_OF_FIELD</td>
<td>Moves the cursor to the beginning of the field.</td>
</tr>
<tr>
<td>START_OF_LINE</td>
<td>Moves the cursor to column 1 of current line.</td>
</tr>
<tr>
<td>TAB</td>
<td>Moves the cursor to the next tab position of the screen.</td>
</tr>
<tr>
<td>TOGGLE_COL_SEP</td>
<td>Toggles the column separator attribute.</td>
</tr>
</tbody>
</table>
The DataCell object provides information about a particular position on a terminal screen.

**Table 5-18 DataCell**

**METHODS**

- **getPosition()**: Returns the position of this data cell on the screen.
  
  Returns
  
  {Position} the position of the data cell on the screen

- **getChar()**: Obtains the character associated with the cell.
  
  Returns
  
  {String} The character associated with the cell.

- **getAttributes()**: Returns the set of attributes specified for this data cell instance. See AttributeSet.
  
  Returns
  
  {AttributeSet} Of attributes for this data cell instance.

- **getForegroundColor()**: Returns the foreground color, as defined in the Color object, for this data cell.
  
  Returns
  
  {Number} Foreground color for this data cell. The color is defined in the Color object.

- **getBackgroundColor()**: Returns the background color, as defined in the Color object, for this data cell.
  
  Returns
  
  {Number} Background color for this data cell. The color is defined in the Color object.

- **toString**: Converts the internal data cell to a string.
  
  Returns
  
  {String} The string representation of a data cell.
**METHODS**

`isFieldDelimiter()` Tests if this cell represents a field delimiter.

Returns

{Boolean} True if this cell is a field delimiter, false if otherwise.

**Dimension**

Represents the size of the screen or screen area.

**Table 5-19  Dimension**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Dimension(rows,cols)</code></td>
<td>Creates a new Dimension instance.</td>
</tr>
</tbody>
</table>

**Parameters**

- `{Number} rows` screen rows dimension
- `{Number} cols` screen columns dimension

**Field**

Use the Field object, along with FieldList, to obtain the information present in a field on the screen.

**Table 5-20  Field**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getAttributes()</code></td>
<td>Returns the set of attributes specified for this field instance. See AttributeSet.</td>
</tr>
</tbody>
</table>

Returns

{AttributeSet} The set of attributes for this field

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getForegroundColor()</code></td>
<td>Returns the foreground color of the field.</td>
</tr>
</tbody>
</table>

Returns

{Number} the foreground color for this field. These values are defined in the Color object.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getBackgroundColor()</code></td>
<td>Returns the background color of the field.</td>
</tr>
</tbody>
</table>

Returns

{Number} the background color for this field. These values are defined in the Color object.
Method

**getStart()**

Returns the starting position of the field. The starting position is the position of the first character of the field. Some host types use a character position to store field level attributes. In this case, the attribute position is not considered the start position.

*Returns*

{Position} Starting position of the field.

*Throws*

{RangeError} For zero length fields.

**getEnd()**

Returns the ending position of the field. The ending position is the position in the presentation space containing the last character of the field.

*Returns*

{Position} Ending position of the field.

*Throws*

{RangeError} For zero length fields.

**getLength()**

Returns the length of the field. For host types that use a character position to store the field attributes, the field length does not include the field attribute position.

*Returns*

{Number} Length of the field.

**getDataCells()**

Obtains the data cells that comprise this field. See DataCell.

*Returns*

{DataCell[]} Data cells that comprise this field.

**getText()**

Obtains the text from the field.

*Returns*

{String} field text.

**setText()**

Sets the field text. For certain host types, like VT, the text is transmitted to the host right away, but in other host types, the text is not transmitted to the host until an Aid key is invoked. If the text is shorter than the field, the text is placed in the host field, and the remainder of the field is cleared. If the text is longer than the host field, then as much text as will fit is placed in the field.

*Parameters*

{String} Text to set on the field.

*Throws*

{Error} If the field is protected.
FieldList

Use the FieldList object, along with Field object, to obtain field list information.

Table 5-21  FieldList

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>clearField()</td>
<td>Clears the current field in an emulation-specific manner.</td>
</tr>
<tr>
<td>getPresentationSpace()</td>
<td>Obtains the PresentationSpace which created this field.</td>
</tr>
<tr>
<td>toString()</td>
<td>Creates a user-friendly description of the field.</td>
</tr>
</tbody>
</table>

Method

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getPresentationSpace()</td>
<td>Obtains the PresentationSpace which created this field list.</td>
</tr>
<tr>
<td>findField(position, text, direction)</td>
<td>Returns the field containing the specified text. The search starts from the specified position and proceeds either forward or backward. If the string spans multiple fields, the field containing the starting position is returned. When searching forward the search will not wrap to the top of the screen. When searching backward the search will not wrap to the bottom of the screen.</td>
</tr>
</tbody>
</table>

Parameters

- {Position} Position from which to start the search. See Position object.
- {String} The text to search for (optional). If not provided, returns the next field to the right of or below the specified position.
- {Number} direction of the search (optional). Use PresentationSpace.SearchDirection constants for this parameter. For example, PresentationSpace.SearchDirection.FORWARD or PresentationSpace.SearchDirection.BACKWARD. If not provided, searches forward.

Returns

- {Field} containing the string or null if a field meeting the given criteria is not found.

Throws

- {RangeError} If the position is out of range.
A fileTransferFactory object is available to all macros. If file transfers are configured for the session, you can use it to get a reference to a FileTransfer object.

**Table 5-22  fileTransferFactory**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>get(index)</td>
<td>Obtains the field at the given index.</td>
</tr>
<tr>
<td>Parameters</td>
<td></td>
</tr>
<tr>
<td>{Number} index into the field list.</td>
<td></td>
</tr>
<tr>
<td>Returns</td>
<td>{Field} located at the specified index.</td>
</tr>
<tr>
<td>Throws</td>
<td>{RangeError} If the index is out of range.</td>
</tr>
<tr>
<td>isEmpty()</td>
<td>Determines if the field list is empty.</td>
</tr>
<tr>
<td>Returns</td>
<td>{Boolean} True if the list is empty.</td>
</tr>
<tr>
<td>size()</td>
<td>Indicates the number of fields in the list.</td>
</tr>
<tr>
<td>Returns</td>
<td>{Number} The field count</td>
</tr>
<tr>
<td>toString()</td>
<td>Creates a user-friendly description of the field list.</td>
</tr>
<tr>
<td>Returns</td>
<td>{String} User readable rendition of the field list.</td>
</tr>
</tbody>
</table>

**FileTransferFactory**

Use the FileTransfer object to list and transfer files between the host system and the client.

The Reflection ZFE file transfer API abstracts the file path conventions used by different host file implementations. Follow URL or Linux file system path formats when formatting file paths used by the API. For example, `/root/directory/file`. It is important to observe any rules specific to host systems, such as allowable characters or name lengths.
**NOTE:** Browsers place significant security restrictions around the ability of Javascript to interact with client file systems.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getHostFileListing(remotePath)</code></td>
<td>Request a listing of host files. If <code>remotePath</code> is omitted, a file listing for the current remote working directory is shown.</td>
</tr>
<tr>
<td>Parameters</td>
<td>`{String} (optional) If specified will get file listing for specified remote path. If not specified, will get file listing for current remote working directory.</td>
</tr>
<tr>
<td>Returns</td>
<td><code>{Promise} Resolves to an array of HostFile objects contained at </code>remoteName`. Rejected if the remote path cannot be read.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sendFile(localFile, remoteName)</code></td>
<td>Sends specified file to the host.</td>
</tr>
</tbody>
</table>
| Parameters | `{File} Javascript file object pointing to local file to send.  
{String} Fully-qualified remote file name as allowed by remote system (Unix, Windows, MVS, VAX). |
| Returns | `{Promise} fulfilled with a HostFile object representing the sent file on success. Rejected if an error occurred sending the file. |

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getDownloadURL(remoteName)</code></td>
<td>Constructs a link to download a file from a host system.</td>
</tr>
<tr>
<td>Parameters</td>
<td>`{String} Fully-qualified remote file name as allowed by remote system (Unix, Windows, MVS, VAX).</td>
</tr>
<tr>
<td>Returns</td>
<td>`{URL} that can be used to retrieve the file from the Reflection ZFE session server.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>setTransferOptions(options)</code></td>
<td>Set transfer options for current FileTransfer session. The transfer options are applied to all future transfers until the session is either exited or overridden by another call to <code>setTransferOptions</code>.</td>
</tr>
<tr>
<td>Parameters</td>
<td>`{JSON} see FileTransferOptions for allowed names and values.</td>
</tr>
<tr>
<td>Returns</td>
<td>`{Promise} fulfilled when the call completes. Rejected if an error occurred setting the options.</td>
</tr>
</tbody>
</table>
**Method**

cancel()  
Cancels the current transfer in progress.

**Returns**

{Promise} fulfilled when the call completes. Rejected if an error occurred canceling the transfer.

---

**HostFile**

A HostFile object represents a file on the host file system.

**Table 5-24  HostFile**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getName()</td>
<td>Gets the file name</td>
</tr>
<tr>
<td>getParents()</td>
<td>Gets the parent of this host file</td>
</tr>
<tr>
<td>getSize()</td>
<td>The byte size of the file</td>
</tr>
<tr>
<td>getType()</td>
<td>The type of file represented</td>
</tr>
</tbody>
</table>

**Returns**

- {String} the file name.
- {String} the parent of this host file. This means different things on different host types. For example on TSO this is the name of the catalog in which the file resides.
- {Number} the size of the file in bytes.
- Value Description
  - FILE Represents a file on the host system.
  - DIR Represents a directory on the host system.
  - UNKNOWN Represents a host file of unknown origin.

**File Transfer Options**

File transfer option object specification.

Example: fileTransfer.setTransferOptions({ transferMethod : 'ascii' });
### Table 5-26  FileTransferOptions

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>transferMethod</td>
<td>(String) Allowed values:</td>
</tr>
<tr>
<td></td>
<td>- 'ascii'</td>
</tr>
<tr>
<td></td>
<td>- 'binary'</td>
</tr>
</tbody>
</table>

### OIA

Operator Information Area (OIA) interface. The OIA object returns values which are defined in the OIAStatus object.

### Table 5-27  OIA

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getstatus()</td>
<td>Returns the set of enabled status flags. See StatusSet.</td>
</tr>
<tr>
<td>Parameters</td>
<td>Returns {StatusSet} Containing the status information.</td>
</tr>
<tr>
<td>getCommErrorCode()</td>
<td>Returns the current communication error code.</td>
</tr>
<tr>
<td>Returns</td>
<td>Returns {Number} the current communication error code. If one doesn't exist, it will be 0.</td>
</tr>
<tr>
<td>getProgErrorCode()</td>
<td>Returns the current program error code</td>
</tr>
<tr>
<td>Returns</td>
<td>Returns {Number} the current program error code. If one doesn't exist, it will be 0.</td>
</tr>
</tbody>
</table>

### OIAStatus

<table>
<thead>
<tr>
<th>OIAStatus</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTROLLER_READY</td>
<td>Controller ready</td>
</tr>
<tr>
<td>A_ONLINE</td>
<td>Online with a non-SNA connection</td>
</tr>
<tr>
<td>MY_JOB</td>
<td>Connected to a host application</td>
</tr>
<tr>
<td>OP_SYS</td>
<td>Connected to a SSCP (SNA)</td>
</tr>
<tr>
<td>UNOWNED</td>
<td>Not connected</td>
</tr>
<tr>
<td>TIME</td>
<td>Keyboard inhibited</td>
</tr>
<tr>
<td>SYS_LOCK</td>
<td>System lock following AID key</td>
</tr>
</tbody>
</table>
Some mainframe hosts have a Digital Certificate Access Server (DCAS). You can request a temporary, one-time pass ticket from DCAS for logging into a host application. Using this object, you can write and configure a macro to run when the session starts and to automatically log you in using the credentials of the currently logged in Reflection ZFE user.

### Table 5-29  AutoSignon

<table>
<thead>
<tr>
<th>OIAStatus</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMM_CHECK</td>
<td>Communication check</td>
</tr>
<tr>
<td>PROG_CHECK</td>
<td>Program check</td>
</tr>
<tr>
<td>ELSEWHERE</td>
<td>Keystroke invalid at cursor location</td>
</tr>
<tr>
<td>FN_MINUS</td>
<td>Function not available</td>
</tr>
<tr>
<td>WHAT_KEY</td>
<td>Keystroke invalid</td>
</tr>
<tr>
<td>MORE_THAN</td>
<td>Too many characters entered in the field</td>
</tr>
<tr>
<td>SYM_MINUS</td>
<td>Symbol entered not available</td>
</tr>
<tr>
<td>INPUT_ERROR</td>
<td>Operator input error (5250 only)</td>
</tr>
<tr>
<td>DO_NOT_ENTER</td>
<td>Do not enter</td>
</tr>
<tr>
<td>INSERT</td>
<td>Cursor in insert mode</td>
</tr>
<tr>
<td>GR_CURSOR</td>
<td>Cursor in graphics mode</td>
</tr>
<tr>
<td>COMM_ERR_REM</td>
<td>Communications error reminder</td>
</tr>
<tr>
<td>MSG_WAITING</td>
<td>Message waiting indicator</td>
</tr>
<tr>
<td>ENCRYPT</td>
<td>Session is encrypted</td>
</tr>
<tr>
<td>NUM_FIELD</td>
<td>Invalid character in numeric only field</td>
</tr>
</tbody>
</table>

### AutoSignon

Some mainframe hosts have a Digital Certificate Access Server (DCAS). You can request a temporary, one-time pass ticket from DCAS for logging into a host application. Using this object, you can write and configure a macro to run when the session starts and to automatically log you in using the credentials of the currently logged in Reflection ZFE user.

### Table 5-29  AutoSignon

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getPassTicket()</td>
<td>Obtains a pass ticket to be used for signing onto a mainframe application. Multiple pass tickets may be requested using different application IDs.</td>
</tr>
</tbody>
</table>

**Parameters**

- `{String}` application ID tells the host which application the sign on is for

**Returns**

- `{Promise}` fulfilled with the pass ticket key or rejected if the operation fails. The pass ticket obtained from DCAS only works with the current host session and is valid for ten minutes.
Using Reflection ZFE

Position

Represents a row and column on the screen.

Table 5-30  Position

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Position(row, col)</td>
<td>Creates a new Position instance.</td>
</tr>
</tbody>
</table>

PresentationSpace

Use the PresentationSpace object to interact with the terminal screen. Setting and getting the cursor position, sending keys, and reading text are some of the interactions available.
Table 5-31 PresentationSpace

METHODS

getCursorPosition()

Returns a Position instance representing the current cursor position. An unconnected session has a cursor position of 0,0.

Returns

{Position} current cursor location

setCursorPosition(position)

Moves the host cursor to the specified row and column position. For some hosts, such as VT, the host may constrain the movements of the cursor.

Parameters

{Position} Position new cursor position.

Returns

None

Throws

{RangeError} If the position is not valid on the current screen.

isCursorVisible()

Tests that the cursor is currently visible in the presentation space. The cursor is considered not visible if the session is not connected.

Returns

{Boolean} True if the cursor is visible. False if the cursor is not visible.

sendKeys(keys)

Transmits a text string or ControlKey to the host at the current cursor position in the presentation space. If the cursor is not in the desired position, then use setCursorPosition function first.

The text string can contain any number of characters and ControlKey objects.

For example: "myname" + ControlKey.TAB + "mypass" + ControlKey.ENTER will transmit a user ID, tab to the next field, transmit a password, and then transmit the Enter key.

If you need to transmit a square bracket, double the brackets ([[ or ]]).

Parameters

{String} keys text and/or control keys to transmit
METHODS

`getText(start, length)`

Returns a string representing a linear area of the presentation space. No new line characters are inserted if row boundaries are encountered.

**Parameters**

- `{Position}` start position from which to retrieve text
- `{Number}` length the maximum number of characters to return. If the length parameter causes the last position of the presentation space to be exceeded then only those characters up to the last position will be returned.

**Returns**

- `{String}` representing a linear area of the presentation space which may be empty if the session is not connected.

**Throws**

- `{RangeError}` If the position or length are not valid on the current screen.

`getSize()`

Gets the dimensions of the screen as a Dimension object.

**Returns**

- `{Dimension}` Containing the number of rows and columns. The screen size is [row:0, col:0] if the session is not connected.

`getDataCells(start, length)`

Returns DataCell instances where the first member will be for the position specified by the start parameter. The maximum number of DataCell instances in the list is specified by the length parameter.

**Parameters**

- `{Position}` start the first position on the host screen in which to retrieve DataCell instances. See Position.
- `{Number}` length of the maximum number of DataCell instance to be retrieved. If not specified, returns DataCells from the start position to the end of the screen.

**Returns**

- `{DataCell[]}` Instances which may be empty if the session is not connected. If position is not specified, returns all DataCells. If length is not specified, returns DataCells from the start position to the end of the screen.

**Throws**

- `{RangeError}` if start or length are out of range.

`getFields()`

Returns a list of the fields in the presentation space. If the host type does not support fields or the current screen is not formatted then the return value will always be an empty list. See FieldList.

**Returns**

- `{FieldList}` of host defined fields in the presentation space.

**Session**

The session object is the main entry point for interacting with the host. It contains functions for connecting, disconnecting, and obtaining the PresentationSpace object.
Table 5-32  Session object functions

<table>
<thead>
<tr>
<th>METHODS</th>

<th>Returns</th>
<th>Parameters</th>
<th>Throws</th>
</tr>
</thead>
<tbody>
<tr>
<td>connect()</td>
<td>Connects to the configured host. If needed, use <code>wait.forConnect()</code> to block macro execution until the session is connected.</td>
<td>None</td>
<td></td>
<td></td>
</tr>
<tr>
<td>disconnect()</td>
<td>Disconnects from the configured host. If needed, use <code>wait.forDisconnect()</code> to block macro execution until the session is connected.</td>
<td>None</td>
<td></td>
<td></td>
</tr>
<tr>
<td>isConnected()</td>
<td>Determines whether the connection to the host is connected.</td>
<td>{Boolean} true if host connection is established; false if not</td>
<td></td>
<td></td>
</tr>
<tr>
<td>getPresentationSpace()</td>
<td>Provides access to the PresentationSpace instance for this session.</td>
<td>{PresentationSpace} instance associated with this session</td>
<td></td>
<td></td>
</tr>
<tr>
<td>getDeviceName()</td>
<td>Returns the device name for a connected session or an empty string if the session is disconnected or doesn't have device name.</td>
<td>{String} The connected device name.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>getType()</td>
<td>Returns the type of host session. See SessionType.</td>
<td>{String} The type of host session.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>setDeviceName()</td>
<td>Provides a means to modify the device name on a session instance.</td>
<td>{String} name Device name to use when connecting to a host.</td>
<td>{Error} If an attempt is made to set the device name while the session is connected.</td>
<td></td>
</tr>
<tr>
<td>getOIA()</td>
<td>Provides access to the OIA instance for this session.</td>
<td>{OIA} Associated with this session</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

SessionType

Constants used to identify the type of host to which the connection is being made. See Session object.
Table 5-33  SessionType

<table>
<thead>
<tr>
<th>Host Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IBM_3270</td>
<td>Indicates an IBM 3270 terminal session.</td>
</tr>
<tr>
<td>IBM_5250</td>
<td>Indicates an IBM 5250 terminal session.</td>
</tr>
<tr>
<td>VT</td>
<td>Indicates a VT session.</td>
</tr>
</tbody>
</table>

StatusSet

You can use the StatusSet object to decode the OIA status. The StatusSet object returns values defined in the OIAStatus object and when used together, you can get status information from the OIA.

Table 5-34  StatusSet

Method

- `contains(statusFlag)`
  Determines if the set contains the specified status flag from OIAStatus constants.
  
  Parameters
  - `{Number} statusFlag` status to check
  
  Returns
  - `{Boolean}` True if the status flag is present in the set.

- `isEmpty()`
  Determines if the status set is empty.
  
  Returns
  - `{Boolean}` True if the set is empty.

- `size()`
  Indicates the number of status flags in the set.
  
  Returns
  - `{Number}` The status count

- `toArray()`
  Converts the internal status set to an array.
  
  Returns
  - `{Object []}` Array of status flags in the set.

- `toString()`
  Converts the internal status set to a string.
  
  Returns
  - `{String}` Space delimited names of status flags in the set.

- `forEach(callback, thisArg)`
  Function to iterate over each element in the status set.
  
  Parameters
  - `{forEachCallback}` Callback to perform the specific operation.
    Called with the name of each status in the set.
  
  - `{Object} thisArg optional pointer to a context object.`
**User Interface**

The user interface object provides functions for interacting with the user, prompting for and displaying basic information. The UI object is made automatically available in your macro as the “ui” variable.

**NOTE:** Important! All UI functions require the ‘yield’ keyword in front of them. This allows the macro to block execution until the conditions of the UI function have been met.

[parameter] denotes an optional parameter.

### Table 5-35  User Interaction

<table>
<thead>

</thead>
<tbody>
<tr>
<td>forEachCallback(string,</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
| thisArg)                | A user provided callback function where you provide the behavior, to be used as the callback parameter to forEach. | **Parameters**  
|                         | {String} String  The name of a status in the status set.                      |                                                                                               | **Returns**                                                                                   |  
|                         | {Object} thisArg  Optional pointer to a context object                      |                                                                                               |                                                                                               |  
| **METHODS**             |                                                                             |                                                                                               |                                                                                               |  
| prompt(message,[defaultAnswer], [mask]) | Prompt the user for information in the user interface,                       | **Parameters**  
|                         | {String} message title to display to the user. Default: blank String.         |                                                                                               | **Returns**                                                                                   |  
|                         | {String} defaultAnswer to use if user leaves it blank. Default: blank String  |                                                                                               |                                                                                               |  
|                         | {Boolean} mask indicates whether to hide the prompt (as with a password).    |                                                                                               |                                                                                               |  
|                         | **Returns**                                                                 | **Returns**                                                                                   |                                                                                               |  
|                         | {Promise} Fulfilled when the user closes the dialog window.                  |                                                                                               |                                                                                               |  
| message([message])      | Display a message in the user interface.                                    | **Parameters**  
|                         | {String} message to display to the user. Default: blank String.              |                                                                                               | **Returns**                                                                                   |  
|                         | **Returns**                                                                 | **Returns**                                                                                   |                                                                                               |  
|                         | {Promise} Fulfilled when the user closes the message window.                 |                                                                                               |                                                                                               |
**Wait**

Use the wait object to wait for a particular session or screen state. For example, you can wait until the cursor is found at a particular location or text is present at a certain location before continuing with the macro execution.

Wait functions are often used in conjunction with asynchronous functions such as connect() and sendKeys().

---

**NOTE:** All functions take timeouts as an optional parameter and have a default time out value of 10 seconds (10000ms).

**Important:** All wait functions require the 'yield' keyword in front of them. This allows the macro to block execution until the conditions of the wait function are met.

[paramater] denotes an optional parameter.

---

</table>

| forConnect([timeout])         | Waits for a connect request to complete.                                    |
| **Parameters**                |                                                                            |
| {Number} in milliseconds      |                                                                            |
| **Returns**                   |                                                                            |
| {Promise}                     | Fulfilled if the session is already connected or when connection occurs.     |
|                               | Rejected if the wait times out.                                             |

| forDisconnect([timeout])      | Waits for a disconnect request to complete.                                  |
| **Parameters**                |                                                                            |
| {Number} timeout in milliseconds |                                                                            |
| **Returns**                   |                                                                            |
| {Promise}                     | Fulfilled if the session is already disconnected or when it finally         |
|                               | disconnects. Rejected if the wait times out.                               |
## METHODS

**forFixedTime([timeout])**

Waits unconditionally for fixed time. Time is in milliseconds (ms)

**Parameters**

{Number} timeout in milliseconds.

**Returns**

{Promise} Fulfilled after time elapses

**forCursor(position, [timeout])**

Waits for the cursor to arrive at the specified position.

**Parameters**

{Position} The position specifying the row and column,

{Number} timeout in milliseconds

**Returns**

{Promise} Fulfilled if the cursor is already located or when it is finally located. Rejected if the wait times out.

**forText(text, position, [timeout])**

Wait for text located at a specific position on the screen

**Parameters**

{String} text to expect

{Position} position specifying the row and column

{Number} timeout in milliseconds

**Returns**

{Promise} Fulfilled if the text is already at the specified position or whenever it is located. Rejected if the wait times out.

**Throws**

{rangeError} if the position is not valid.

**forHostPrompt(text, column, [timeout])**

Waits for a command prompt located at a particular column on the screen.

**Parameters**

{String} text prompt to expect

{Number} column where cursor is expected

{Number} timeout in milliseconds.

**Returns**

{Promise} Fulfilled if the conditions are already met or when the conditions are finally met. Rejected if the wait times out.

**Throws**

{rangeError} if the column is out of range.
Sample Macros

To help you create successful macros that take advantage of all the capabilities of the Macro Editor and Reflection ZFE, these samples are available as a starting point.

- Basic Host Interaction
- User Interaction
- Paging Through Data
- Invoking a Web Service
- Working with DataCells and Attributes
- Using Fields and Field Lists
- Automatic Sign-On Macro for Mainframes
- Using File Transfer (IND$File)

**Basic Host Interaction**

This sample illustrates basic host interaction, including:

- Sending data to the host
- Waiting for screens to display
- Using the `yield` keyword to wait for asynchronous functions
- Reading text from the screen
- Displaying basic information to the user
- Handling error basics

All macros have the following objects available by default:

1. **session** - Main entry point for access to the host. Can connect, disconnect and provides access to the PresentationSpace.
   
   The PresentationSpace object obtained from the session represents the screen and provides many common capabilities such as getting and setting the cursor location, sending data to the host and reading from the screen.

2. **wait** - Provides a simple way to wait for various host states before continuing to send more data or read from the screen.

3. **UI** - Provides basic user interface capabilities. Display data to the user or prompt them for information.

```javascript
// Create a new macro function
var macro = createMacro(function*(){
  'use strict';

  // All macros have the following objects available by default:
  // 1. session - Main entry point for access to the host. Can connect, disconnect and provides access to the PresentationSpace.
  //     The PresentationSpace object obtained from the session represents the screen and provides many common capabilities such as getting and setting the cursor location, sending data to the host and reading from the screen.
  // 2. wait - Provides a simple way to wait for various host states before continuing to send more data or read from the screen.
  // 3. UI - Provides basic User Interaction capabilities. Display data to the user or prompt them for information.

  // Declare a variable for reading and displaying some screen data.
```

126  Using Reflection ZFE
// As a best practice all variables should be declared near the top of a function.
var numberOfAccounts = 0;

// Start by obtaining the PresentationSpace object, which provides many common
screen operations.
var ps = session.getPresentationSpace();

try {
    // Can set and get the cursor location
    ps.setCursorPosition(new Position(24, 2));

    // Use the sendKeys function to send characters to the host
    ps.sendKeys('cics');

    // SendKeys is also used to send host keys such as PA and PF keys.
    // See "Control Keys" in the documentation for all available options
    ps.sendKeys(ControlKey.ENTER);

    // Wait for the cursor to be at the correct position.
    // The wait object provides various functions for waiting for certain states to occur
    // so that you can proceed to either send more keys or read data from the
    // screen.
    yield wait.forCursor(new Position(24, 2));

    // You can mix characters and control keys in one sendKeys call.
    ps.sendKeys('data' + ControlKey.TAB + ControlKey.TAB + 'more data' +
               ControlKey.ENTER);

    // The "yield" keyword must be used in front of all "wait" and "ui" function
    // calls.
    // It tells the browser to pause execution of the macro until the
    // (asynchronous) wait function returns. Consult the documentation for which
    // functions
    // require the yield keyword.
    yield wait.forCursor(new Position(10, 26));
    ps.sendKeys('accounts' + ControlKey.ENTER);

    // Can also wait for text to appear at certain areas on the screen
    yield wait.forText('ACCOUNTS', new Position(3, 36));
    ps.sendKeys('1' + ControlKey.ENTER);

    // All wait functions will timeout if the criteria is not met within a time
    // limit.
    // Can increase timeouts with an optional parameter in the wait functions (in
    // milliseconds)
    // All timeouts are specified in milliseconds and the default value is 10
    // seconds (10000ms).
    yield wait.forCursor(new Position(1, 1), 15000);
    ps.sendKeys('A' + ControlKey.ENTER);

    // PS provides the getText function for reading text from the screen
    numberOfAccounts = ps.getText(new Position(12, 3), 5);

    // Use the ui object to display some data from the screen
    ui.message('Number of active accounts: ' + numberOfAccounts);
// The try / catch allows all errors to be caught and reported in a central location
} catch (error) {
  // Again we use the ui object to display a message that an error occurred
  yield ui.message('Error: ' + error.message);

} //End Generated Macro

// Run the macro and return the results to the Macro Runner
// The return statement is required as the ZFE application leverages
// this to know if the macro succeeded and when it is finished
return macro();

User Interaction

This sample illustrates how to use the provided API methods to prompt the user for input or alert them with a message.

var macro = createMacro(function*() {
  'use strict';

  // The "ui" object provides functions for prompting the user for information and displaying information
  // Declare variables for later use
  var username;
  var password;
  var flavor;
  var scoops;

  //Begin Generated Macro
  var ps = session.getPresentationSpace();

  try {
    // Prompt the user to enter their name and store it in a variable.
    // Note that 'yield' keyword is needed to block execution while waiting for the user input.
    username = yield ui.prompt('Please enter your username');

    // Prompt the user to enter a value with a default provided to them.
    flavor = yield ui.prompt('What is your favorite flavor of ice cream?', 'Chocolate');

    // Prompt the user to enter private information by using the 'mask' option and the input field will be masked as they type.
    // If a parameter is not used, 'null' can be used to specify that it isn't to be used.
    // Here we illustrate that by specifying that we don't need to show a default value.
    password = yield ui.prompt('Please enter your password', null, true);

    // The prompt function returns null if the user clicks the 'Cancel' button instead of the 'OK' button.
    // One way to handle that case is to wrap the call in a try/catch block.
    scoops = yield ui.prompt('How many scoops would you like?');
    if (scoops === null) {
      // This will exit the macro.
      return;
    }
  }

  // End Generated Macro
});
Using Reflection ZFE

Paging Through Data

This sample illustrates how to page through a variable number of screens and process the data on each screen.

try {
    // Create a new macro function.
    var macro = createMacro(function*(){
        'use strict';

        // Create variable(s) for later use
        var password;
        var accountNumber;
        var transactionCount = 0;
        var row = 0;

        // Obtain a reference to the PresentationSpace object.
        var ps = session.getPresentationSpace();

        try {
            // Enter Username and Password to log on to the application.
            yield wait.forCursor(new Position(19, 48));
            ps.sendKeys('bjones' + ControlKey.TAB);
            yield wait.forCursor(new Position(20, 48));
            password = yield ui.prompt('Password:', null, true);
            ps.sendKeys(password);
            ps.sendKeys(ControlKey.ENTER);

            // Enter an application command.
            yield wait.forCursor(new Position(20, 38));
            ps.sendKeys('4');
            ps.sendKeys(ControlKey.ENTER);

            // Going to list transactions for an account.
            yield wait.forCursor(new Position(13, 25));
            ps.sendKeys('2');
            // Input an account number. Hard coded here for simplicity.
            yield wait.forCursor(new Position(15, 25));
            accountNumber = yield ui.prompt('Account Number:', '167439459');
            ps.sendKeys(accountNumber);
            ps.sendKeys(ControlKey.ENTER);

            // Wait until on account profile screen
            yield wait.forText('ACCOUNT PROFILE', new Position(3, 33));
        } catch (error) {
            yield ui.message(error.message);
        }
    }
    return macro();
})();
// Search for text that indicates the last page of record has been reached
while (ps.getText(new Position(22, 12), 9) !== 'LAST PAGE') {

    // While the last page of record has not been reached, go to the next page of records.
    ps.sendKeys(ControlKey.PF2);
    yield wait.forCursor(new Position(1, 1));

    // If the cursor position does not change between record screens, and there is no text
    // on the screen you can check to confirm a screen is updated, you may wait for a
    // fixed time period after an aid key is sent for the screen to settle.
    // For example:
    // yield wait.forFixedTime(1000);

    // For each of the rows, increment the count variable if it contains data.
    for (row = 5; row <= 21; row++) {

        // There are 2 columns on the screen. Check data on column 1.
        // In this example we know that if there is a space at a particular
        // position then there is a transaction.
        if (ps.getText(new Position(row, 8), 1) !== ' ') {
            transactionCount++;
        }

        // Check data on column 2.
        if (ps.getText(new Position(row, 49), 1) !== ' ') {
            transactionCount++;
        }
    }

    // After going through all record pages, display the number of records in a message box.
    yield ui.message('There are ' + transactionCount + ' records found for account ' +
                     accountNumber + '.');

    // Log out of the application
    ps.sendKeys(ControlKey.PF13);
    ps.sendKeys(ControlKey.PF12);

    // The try / catch allows all errors to be caught and reported in a central location
    try {
        // Here we use the ui object to display a message that an error occurred
        yield ui.message(error.message);
    } catch (error) {
        // Here we use the ui object to display a message that an error occurred
        yield ui.message(error.message);
    }
}

// Here we run the macro and return the results to the Macro Runner
// The return statement is required as the ZFE application leverages
// this to know if the macro succeeded
return macro();

**Invoking a Web Service**

This sample illustrates how to make an AJAX / REST call directly from a macro to a web service. You
can integrate data from your host application into the web service call or from the web service into
your host application.

In this example, we are calling the Verastream Host Integrator (VHI) CICSAcctsDemo REST service.
However, you can easily adapt the code to call any web service. You are not limited to VHI.

In the example the call goes through a proxy configured in the session server (shown below) to avoid
a “Same Origin Policy” complication. If you are using a web service that supports Cross-origin
Resource Sharing (CORS) and are using a modern browser, the proxy is unnecessary.

Since the jQuery library is available in macros, so you may use the $.post() function directly to invoke
REST services.

This example also demonstrates how to wrap a jQuery REST call in a new Promise. The promise
returned from the custom function below allows "yield" to be used in the main macro code. This
allows the main macro execution to wait until the service call is complete before continuing.
var macro = createMacro(function*() {
    'use strict';

    // Create a few variables for later use
    var username;
    var password;
    var accountNumber;
    var accountDetails;

    // Create a function that will make an AJAX / REST call to a VHI Web Service.
    // Could be adjusted to call any web service, not just VHI.
    // If not using CORS, the request will likely need to pass through a
    // proxy on the session server. See sample notes for more information.
    /**
     * Hand-coded helper function to encapsulate AJAX / REST parameters, invoke the
     * REST service and return the results inside a Promise.
     * @param {Number} acctNum to send to the REST query.
     * @param {String} username to access the REST service.
     * @param {String} password to access the REST service.
     * @return {Promise} containing $.post() results that are compatible with yield.
     */
    var getAccountDetails = function (acctNum, username, password) {
        var url = "proxy1/model/CICSAcctsDemo/GetAccountDetail";
        var args = {"filters": {"AcctNum": acctNum}, "envVars": {"Username": username,
            "Password": password}};

        // Wrap a jQuery AJAX / HTTP POST call in a new Promise.
        // The promise being returned here allows the macro to yield / wait
        // for its completion.
        return Promise.resolve($.post(url, JSON.stringify(args)))
            .catch(function (error) {
                // Map errors that happen in the jQuery call to our Promise.
                throw new Error('REST API Error: ' + error.statusText);
            });
    }

    // Begin Generated Macro
    var ps = session.getPresentationSpace();
    try {
        // Could interact with the host here, log into a host app, etc...
        // Gather username and password
        username = yield ui.prompt('Username:');
        password = yield ui.prompt('Password:', null, true);
        accountNumber = yield ui.prompt('Account Number:');
        if (!username || !password || !accountNumber) {
            throw new Error('Username or password not specified');
        }

        // Invoke external REST service, and yields / waits for the call to complete.
        accountDetails = yield getAccountDetails(accountNumber, username, password);

        // We now have the data from our external service.
        // Can integrate the data into our local host app or simply display it to the user.
        if (accountDetails.result && accountDetails.result.length > 0) {
            yield ui.message(accountDetails.result[0].FirstName + ' $' +
                accountDetails.result[0].AcctBalance);
        } else {
            yield ui.message('No records found for account: ' + accountNumber);
        }
    } catch (error) {
        // If an error occurred during the AJAX / REST call
        // or username / password gathering we will end up here.
        yield ui.message(error.message);
    }

    // Run our macro
    return macro();
}

Cross Origin Scripting Proxy Support
If you have web services that do not support CORS, AJAX/REST calls will fail if they attempt to access a different server than the one where the ZFE application originated. This is a browser security feature.

The Reflection ZFE server provides a way explicitly to proxy to trusted remote servers.

- Open `..\ReflectionZFE\sessionserver\microservice\zfe\service.yml` for editing.
- In the `env` section add:

  ```yaml
  name: zfe.proxy.mappings
  value: proxy-path=proxy-to-address
  ```

  Where `proxy-path` refers to the desired url-mapping and `proxy-to-address` refers to the URL where the call will be proxied.

- In this example:

  ```yaml
  name: zfe.proxy.mappings
  value: proxy1=http://remote-vhi-server:9680/vhi-rs/
  ```

  Calls made to `<server:port>/zfe/proxy1` will be proxied to `http://remote-vhi-server:9680/vhi-rs/`

- Multiple proxy mappings can be specified using a comma to separate the individual proxy mappings
- Keep in mind that even when a REST server supports CORS headers, some older browsers may not, so this example may still be relevant.

**TIP:** Your `service.yml` file may be replaced whenever you redeploy Reflection ZFE. Always back up your files.

---

**Working with DataCells and Attributes**

This macro illustrates how to use DataCells and AttributeSet to inspect a given row/column on the screen for text and attributes. In this sample you can see:

- How to get a collection of DataCells for a given position and length.
- How to iterate through DataCells to build up a text string
- How, for comparison, you can also do a similar thing using `getText()`.
- And finally, how to work with attributes, get a string listing, or determine whether specific ones are set at a given screen location.

```javascript
var macro = createMacro(function*() {
  'use strict';

  // Obtain the PresentationSpace for interacting with the host
  var ps = session.getPresentationSpace();

  // Declare variables for later use
  var cells;
  var text;
  var attrs;

  // Set the default timeout for "wait" functions
  wait.setDefaultTimeout(10000);

  // Sample macro for working with DataCells and Attributes
  try {
    yield wait.forCursor(new Position(24, 2));

    // Get DataCells from the presentation space.
    // Row 19, col 3 is the prompt, 35 characters long
```
// "Choose from the following commands:"
cells = ps.getDataCells({row:19, col:3}, 35);
text = '';

// You can display text using getText
yield ui.message("Screen text: " + ps.getText({row:19, col:3}, 35));

// Or you can assemble the text from the DataCells at each position
for(var index = 0; index < cells.length; index++) {
    text = text.concat(cells[index].getChar());
}
// And display the text
yield ui.message("Cells text: " + text);

// Get the attributes for the first DataCell (cell[0])
attrs = cells[0].getAttributes();

// Display whether we have any attributes on the data cell
yield ui.message("Attribute set is empty: " + attrs.isEmpty());

// Display how many attributes are set
yield ui.message("Number of attributes: " + attrs.size());

// Display which attributes are set
yield ui.message("Attributes: " + attrs.toString());

// Now display whether the high intensity attribute is set
yield ui.message("Is high intensity: " +
    attrs.contains(Attribute.HIGH_INTENSITY));

// Now display whether the underline attribute is set
yield ui.message("Is underline: " +
    attrs.contains(Attribute.UNDERLINE));

// Now display whether alphanumeric, intensified and pen-detectable attributes are set
yield ui.message("Is alphanumeric, intensified and pen-detectable: " +
    attrs.containsAll([Attribute.ALPHA_NUMERIC, Attribute.HIGH_INTENSITY,
    Attribute.PEN_DETECTABLE]));

// Now display whether underline, intensified and pen-detectable attributes are set
yield ui.message("Is underline, intensified and pen-detectable: " +
    attrs.containsAll([Attribute.UNDERLINE, Attribute.HIGH_INTENSITY,
    Attribute.PEN_DETECTABLE]));

// End Generated Macro

// Run the macro
return macro();

Using Fields and Field Lists

This macro sample illustrates how to use common functions to interact with the fields in the Macro API. For example, how to get field text, view field information, and how to use field.setText as an alternative to sendKeys to interact with the host.

---

**NOTE:** Due to browser considerations ui.message collapses strings of spaces down to a single space. The spaces are preserved in the actual JavaScript.
```javascript
var macro = createMacro(function() {
  'use strict';

  // Obtain the PresentationSpace for interacting with the host
  var ps = session.getPresentationSpace();

  // Declare variables for later use
  var fields;
  var field;
  var searchString = 'z/VM';

  // Set the default timeout for "wait" functions
  wait.setDefaultTimeout(10000);

  // Sample macro for working with FieldList and Fields
  try {
    yield wait.forCursor(new Position(24, 2));

    // Get the field list.
    fields = ps.getFields();

    // Run through the entire list of fields and display the field info.
    for(var index = 0; index < fields.size(); index++) {
      field = fields.get(index);

      yield ui.message("Field "+index + " info: " + field.toString());
    }

    yield ui.message("Now, find a field containing the text " + searchString + "]
    if(field !== null) {
      yield ui.message("Found field info: " + field.toString());
      yield ui.message("Found field foreground is green? " + (Color.GREEN === field.getForegroundColor()));
      yield ui.message("Found field background is default? " + (Color.BLANK_UNSPECIFIED === field.getBackgroundColor()));
    }

    // Now, find command field and modify it.
    field = fields.findField(new Position(23, 80));
    if(field !== null) {
      field.setText("cics");
    }

    yield ui.message("Click to send 'cics' to host.");
    ps.sendKeys(ControlKey.ENTER);

    // Wait for new screen; get new fields.
    yield wait.forCursor(new Position(10, 26));
    fields = ps.getFields();

    // Find user field and set it.
    field = fields.findField(new Position(10, 24));
    if(field !== null) {
      field.setText("myusername");
    }

    // Find password field and set it.
    field = fields.findField(new Position(11, 24));
    if(field !== null) {
      field.setText("mypassword");
    }

    yield ui.message("Click to send login to host.");
    ps.sendKeys(ControlKey.ENTER);

    // Wait for new screen; get new fields.
    yield wait.forCursor(new Position(1, 1));
    fields = ps.getFields();

    // Find command field and set logoff command.
    field = fields.findField(new Position(24, 45));
  }

  var ps = session.getPresentationSpace();

  // Declare variables for later use
  var fields;
  var field;
  var searchString = 'z/VM';

  // Set the default timeout for "wait" functions
  wait.setDefaultTimeout(10000);

  // Sample macro for working with FieldList and Fields
  try {
    yield wait.forCursor(new Position(24, 2));

    // Get the field list.
    fields = ps.getFields();

    // Run through the entire list of fields and display the field info.
    for(var index = 0; index < fields.size(); index++) {
      field = fields.get(index);

      yield ui.message("Field "+index + " info: " + field.toString());
    }

    yield ui.message("Now, find a field containing the text " + searchString + "]
    if(field !== null) {
      yield ui.message("Found field info: " + field.toString());
      yield ui.message("Found field foreground is green? " + (Color.GREEN === field.getForegroundColor()));
      yield ui.message("Found field background is default? " + (Color.BLANK_UNSPECIFIED === field.getBackgroundColor()));
    }

    // Now, find command field and modify it.
    field = fields.findField(new Position(23, 80));
    if(field !== null) {
      field.setText("cics");
    }

    yield ui.message("Click to send 'cics' to host.");
    ps.sendKeys(ControlKey.ENTER);

    // Wait for new screen; get new fields.
    yield wait.forCursor(new Position(10, 26));
    fields = ps.getFields();

    // Find user field and set it.
    field = fields.findField(new Position(10, 24));
    if(field !== null) {
      field.setText("myusername");
    }

    // Find password field and set it.
    field = fields.findField(new Position(11, 24));
    if(field !== null) {
      field.setText("mypassword");
    }

    yield ui.message("Click to send login to host.");
    ps.sendKeys(ControlKey.ENTER);

    // Wait for new screen; get new fields.
    yield wait.forCursor(new Position(1, 1));
    fields = ps.getFields();

    // Find command field and set logoff command.
    field = fields.findField(new Position(24, 45));
```
if(field !== null) {
    field.setText("cesf logoff");
}

yield ui.message("Click to send logoff to host.");
ps.sendKeys(ControlKey.ENTER);

} catch (error) {
    yield ui.message(error);
}

//End Generated Macro

// Run the macro
return macro();

**Automatic Sign-On Macro for Mainframes**

In this example the Autosignon object is used to create a macro that uses the credentials associated with a user to obtain a pass ticket from the Digital Certificate Access Server (DCAS).

var macro = createMacro(function*() {
    'use strict';

    // Obtain the PresentationSpace for interacting with the host
    var ps = session.getPresentationSpace();

    // Variable for login pass ticket
    var passTicket;

    // Login application ID
    var appId = 'CICSV41A';

    // Set the default timeout for "wait" functions
    wait.setDefaultTimeout(10000);

    // Begin Generated Macro
    try {
        yield wait.forCursor(new Position(24, 2));

        // Obtain a pass ticket from DCAS.
        passTicket = yield autoSignon.getPassTicket(appId);

        ps/sendKeys('cics');
        ps.sendMessage(ControlKey.ENTER);

        yield wait.forCursor(new Position(10, 26));

        // Replace generated username with sendUserName(passTicket) ...
        yield autoSignon.sendUserName(passTicket);

        // ps/sendKeys('bvtst01' + ControlKey.TAB + ControlKey.TAB);
        ps/sendKeys(ControlKey.TAB + ControlKey.TAB);

        yield wait.forCursor(new Position(11, 26));

        // Replace generated password with sendPassword(passTicket) ...
        yield autoSignon.sendPassword(passTicket);

        // var userInput3 = yield ui.prompt('Password:', '', true);
        // if (userInput3 === null) {
        //     throw new Error('Password not provided');
        // }
        // ps/sendKeys(userInput3);
Using File Transfer (IND$File)

This series of sample macros demonstrate how to use the File Transfer API to retrieve a list of files, download a file, and upload a file to a 3270 host.

**NOTE:** You must be logged in and at a ready prompt before running these macros.

### List files

This macro demonstrates how to use the File Transfer API to retrieve a list of files on a 3270 host using IND$File transfer. The IND$File transfer object is retrieved from the file transfer factory and then used to obtain an array of HostFile objects from either TSO or CMS.

```javascript
var macro = createMacro(function*() {
  'use strict';
  try {
    var fileTransfer = fileTransferFactory.getInd$File();
    var hostFiles = yield fileTransfer.getHostFileListing();
    yield ui.message('Found ' + hostFiles.length + ' files');
    if (hostFiles.length > 0) {
      var firstFile = hostFiles[0];
      var msg1 = 'The catalog name is ' + firstFile.getParent() + '.  '
      var msg2 = 'The first file is ' + firstFile.getName();
      yield ui.message(msg1 + msg2);
    } 
  } catch (error) {
    yield ui.message(error);
  }
  // Run the macro
  return macro();
});
```

### Download file

This macro shows how to use the File Transfer API to download a file from a 3270 host using IND$File transfer. The IND$File transfer object is retrieved from the file transfer factory. In this example the transfer method is set to ASCII to demonstrate use of the setTransferOptions function. The sample macro downloads the first file returned from a call to getHostFileListing by creating a download URI with a call to the getDownloadUrl function.

The macro can be used in either a CMS or TSO environment but the choice must be specified on the first line or the code modified slightly for the intended system.
var hostEnvironment = 'CMS'; // 'TSO'

// Construct file path, ie catalog/file.name or catalog/partition/file
function getPath (fileNode) {
    var prefix = fileNode.getParent() ? fileNode.getParent() + '/' : '';
    return prefix + fileNode.getName();
}

var macro = createMacro(function*() {
    'use strict';
    try {
        var fileTransfer = fileTransferFactory.getInd$File();

        // The transferMethod options are 'binary' and 'ascii'
        fileTransfer.setTransferOptions({transferMethod: 'ascii'});

        // This demo retrieves the first file returned in the listing
        var hostFiles = yield fileTransfer.getHostFileListing();
        var firstHostFile = hostFiles[0];

        if (hostEnvironment === 'CMS') {
            yield wait.forText('Ready', new Position(1,1), 5000);
        }

        // If you already know the path of the file you want, just pass that to
        getDownloadURL()
        var downloadUrl = fileTransfer.getDownloadURL(getPath(firstHostFile));

        // This changes the browser location. You may experience different results on
        different browsers
        window.location = downloadUrl;

        // If you want to read the file contents into a variable instead of downloading
        // it, you can use jQuery
        // var fileContents = yield $.get(downloadUrl);
    } catch (error) {
        yield ui.message(error);
    }
});

// Run the macro
return macro();

Upload file

This macro illustrates how to use the File Transfer API to upload a file to a 3270 host using INDF$File
transfer. The sample macro prompts the user to choose a file from the local file system by triggering
the browser’s file selection dialog. It then retrieves the current catalog on TSO or drive identifier on
CMS by calling getHostFileListing. Finally, the sendFile function is called to deliver the selected local
file to the host.

The macro can be used in either a CMS or TSO environment but the choice should be specified on
the first line. In this example, the transfer method is set to ascii; you may want to change this to
binary.

var hostEnvironment = 'CMS'; // 'TSO'

// Open the browser's file chooser dialog programmatically
function promptForFileToUpload () {
    return new Promise(function (resolve, reject) {
        // We are not notified if the user cancels the file chooser dialog so reject after 30
        seconds
        var timerId = setTimeout(reject.bind(null, 'Timed out waiting for file selection'),
            30000);

        var fileSelector = document.createElement('input');
        fileSelector.setAttribute('type', 'file');
        fileSelector.onchange = function (evt) {
            var file = evt.target.files[0];
            clearTimeout(timerId);
            resolve(file);
        }
    });
}
Using Reflection ZFE

```javascript
});
fileSelector.click();
});
}

var macro = createMacro(function*() {
  'use strict';
  try {
    var fileTransfer = fileTransferFactory.getInd$File();
    // The transferMethod options are 'binary' and 'ascii'
    fileTransfer.setTransferOptions({transferMethod: 'ascii'});
    var localFile = yield promptForFileToUpload();
    // Retrieve the current catalog name and append the selected file name to it
    var hostFiles = yield fileTransfer.getHostFileListing();
    var destination = hostFiles[0].getParent() + '/' + localFile.name;
    if (hostEnvironment === 'CMS') {
      yield wait.forText('Ready', new Position(1,1), 5000);
    }
    var result = yield fileTransfer.sendFile(localFile, destination);
  } catch (error) {
    yield ui.message(error);
  }
});
// Run the macro
return macro();
```

Logging Out

In the upper right corner of the screen, open the drop down list associated with your user name and select Logout to stop working with the host application.

Printing

There are various printing options available:

- Capture a screen
- Print a screen
- 3270 Host Printing

The settings available to you regarding page setup and orientation are dependent on your browser options.

Capture a screen

Use the screen capture feature to capture multiple screens then save them as a file for printing or sharing. This option is available to all users once the administrator selects it using User Preferences.

1. Navigate to the screen you want to capture.

2. Click 📷 to capture the screen. The counter displays the number of captures you’ve taken. Each capture will print to a separate page.
3 Click Save to browse to the location where you want to save the capture. Your browser determines how the save option functions. For example, in Chrome, depending on your browser settings, the file will be saved in the download file or you will see a Save As dialog to select a location to save the captured file.

4 To append your newly saved screens to an existing screen capture file, click Append and save. When you print the appended file, each screen capture is printed to a separate page.

5 You can clear the captures whenever you want by clicking Clear.

Print a screen

The print screen option prints the contents of the terminal screen. It does not print the toolbar or other display information.

1 Navigate to the screen you want to print.
2 Click Print Screen on the tool bar.
3 Use your browser’s print dialog to select the printer and page setup options.

3270 Host Printing

This feature is available to 3270 host sessions. You can create one or more 3287 printer sessions and associate them with the current 3270 terminal session. Each printer session is bound to a Logical Unit (LU) on the host system and any subsequent print jobs sent to that LU will be directed to the Reflection ZFE web client.

The 3287 session builds a PDF file that contains the file to print and sends it to the Reflection ZFE web client. After receiving the file, the Reflection ZFE web client downloads the file following your browser’s configured download options. Different browsers provide different options for handling downloaded files. When the PDF file is received, you can direct it to any printer that you have access to.

NOTE: An administrator can provide end users with the ability to print by setting the Host Printing User Preferences option.

</tr>
<tr>
<td></td>
<td>• <strong>Specify Host LU Name</strong> - Specify the name of the host LU (logical unit) to use when the session connects to the host. The host LU is also known as the device name.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Use TN Association</strong> - (TN3270E) If you choose to use a TN association, Reflection ZFE uses the device name specified in the connection settings to link the 3270 and 3287 session together. TN Association is only available if you select TN3270E as the protocol.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Prompt the user</strong> - When the session connects, the user is prompted to supply the LU Name for the printer session.</td>
</tr>
</tbody>
</table>

Page Setup settings

The Page Setup tab contains setting options for paper size and orientation, along with dimensions, margins, and scaling values.
There are three options available to you when deciding when to download the PDF file.

- **Automatically** - (default) The PDF is downloaded automatically when the print job is complete. When this option is selected, the Inactivity timeout setting is not available.

- **Manually** - Once a print job commences, you can initiate a download anytime by locating the print job in the download list available from the Print icon on the tool bar and clicking **Flush**. The print job is aggregated into a single PDF file and downloaded.

- **After inactivity timeout** - Using this option you can print multiple print jobs, have them aggregated into a single PDF, and then automatically downloaded when you specify.

  If you decide on a value greater than 0 (for example, 5 seconds) any print jobs assigned to a printer that arrive within 5 seconds of each other will be appended to the same PDF. After 5 seconds and no remaining print jobs, the PDF is downloaded. If you specify 0 for the inactivity timeout, each print job is downloaded immediately upon completion. You can always interrupt a print job by clicking **Flush**.

To print your 3270 printer session

When the terminal session opens, you can now:

1. Select the printer session you want to use. All print sessions associated with the opened terminal session are available to you. Click on the tool bar to see a list.

2. The 3287 session receives the print data from the host and builds a PDF file to print. A link to this file is sent to the Reflection ZFE web client indicating it is available for download. You can monitor the various print jobs using the tool bar page counter or the counter associated with separate printers in the print drop down list. The page counter on the tool bar reflects the total number of pages either being actively printed or complete but waiting for the file to download from the server. You can trigger a download by selecting Flush from the printer list. The page counter attached to printers in the printer drop down list displays the same value but on a per printer basis. The sum of these separate print jobs is reflected in the tool bar count. The count is cleared once the print jobs are downloaded.

3. After the PDF file becomes available, the file either begins downloading or waits for you to trigger a download using the Flush option, depending on the options you configured. If necessary, due to an overlong running print job or some other issue, you can flush your current print job. The Flush option is available from the list of printer sessions accessed from the printers icon on the tool bar. When you flush a print job, whatever has been accumulated so far is printed and processing of print data continues.

Customize Sessions

You can use these features to customize sessions for your end users:

- **Plus** - Enable custom controls to provide a more efficient work flow and a more modern and friendly interface. See Use Plus to customize screens. Using this option, you can add tool tips to fields, replace old-style numbered lists with more modern drop-down lists, add buttons to the host interface and program them to start macros or perform other actions, and replace manual date entry with a graphical calendar date-picker.

- **Server-side Events** - Supply procedural Java code that extends and improves the presentation of host data. Using server side events, you can define specific events and suspend the host application, replacing or interrupting it with code that you have supplied to the session, as well as extend error handling options. For example, you can add an event that recognizes when an error occurs and then implements the code to intercept the error, take control, and correct the error. See Use server side events.

- **Advanced** - Only use as directed by Micro Focus Technical Support.

These options are configured on the Customization panel.

1. Click Settings on the toolbar to open the left navigation panel.
2. Click Customization.

**Related Topics**
Use Plus to customize screens
Use server side events

Use Plus to customize screens

**NOTE:** The Plus feature requires archive files (.rdar) produced by Micro Focus Screen Designer version 9.5 or higher. The Screen Designer is available in Micro Focus Rumba Desktop 9.5. Reflection Desktop 16.1 includes a limited version of the Screen Designer. To get access to more controls and full use of Plus and the Screen Designer, you can purchase and install the Micro Focus Reflection Desktop Plus add-on.

1. On the **Customization** panel, click **Enable Plus**.
2. Select the Plus archive file you want to use from the drop down list or upload a file from a different location. Plus archive files are identified by a `.rdar` file extension.
   
   Archive files are the output of a Screen Designer project and are used to provide the custom control criteria.
   
   If you are updating the Plus archive (.rdar) file associated with your Plus enabled session, you must first delete the folder containing the old .rdar file from the session server. After you delete the folder, you can open your Plus enabled session and the new rdar file will be downloaded to the session server.
3. Verify the number of milliseconds for the host settle delay time is accurate. This is the time that the server waits for a synchronous connection before deciding that the host has finished sending data.
4. When you return to your session, Plus is available. Click on the toolbar to turn off the custom controls.

When you enable Plus for a session, all end users of that session see the Plus icon on the toolbar and any controls made available through the Screen Designer customization file.

**Related Topics**

**Customize Sessions**

Use server side events

Using server side events, you can supply procedural Java code that can extend and improve the presentation of host data.

The **Customization** panel tells the web client where to find the event after you’ve configured it. See Using the ZFE Java SDK for instructions on using the SDK and the samples available to you.

1. Open the **Customization** panel.
2. Under **Server Side Events** type the fully qualified class name to the event.
3. Launch the session and test the event.

Access API documentation and event samples
Set User Preferences

As an administrator you can choose what options users can configure for their sessions. These options are set on a per session basis and all users who have access to a particular session can configure their own session instance.

1. From the left navigation panel, choose User Preference Rules.
2. Select which options you want to allow your users to configure.
3. Click Save.

Each user’s configurations are specific to their instance of the session and will not conflict with those of other users.
Developing with Reflection ZFE

ZFE has a collection of APIs and libraries that help you develop efficient client/server and Web applications that integrate host data into various development environments.

You can also extend the web client without affecting the installed files. This ability provides you with a wide range of options to tailor the web client to your own needs.

- **Using the ZFE Java SDK** you can use the provided Java API to enhance the presentation of host data using server side events.
- **Using the ZFE Connector for Windows** you can interact with host sessions in your .NET application or within Visual Basic for Applications using the API and samples provided.
- **Using the ZFE JavaScript API** you can embed the web client in your own web site.
- **Extending the ZFE Web Client** you can enhance and broaden the scope of the web client using custom code, such as CSS or JavaScript.

**View API Documentation**

**Using the ZFE Java SDK**

Working with server side events and the Reflection ZFE SDK you can supply procedural Java code that can extend and improve the presentation of host data. To help you create server side events, Reflection ZFE has an SDK and samples that can provide you with a starting point.

The Javadocs are available in your installation directory (`<install dir>\sessionserver\sdk\java\javadocs\index.html`) as well as online.

1. Make the Reflection ZFE SDK available to your development environment. The SDK is available at `install-dir\Micro Focus\ReflectionZFE\sessionserver\sdk`.
2. Write the Java code necessary to accomplish the task and compile the code into a Java class within a JAR (Java Archive) file.
3. Copy the JAR file to `<install-dir>\Micro Focus\ReflectionZFE\sessionserver\microservices\zfe\extensions\server` and restart the session server.
   
   If you have more than one session server on which you want the event to run, you must copy the JAR file to this location on each server.
4. Add the session you want to associate with the event in the Administrative Console.
5. As you configure the session in the Reflection ZFE web client, open the Customization panel and type the fully qualified class name to the event.
6. Launch the session and test the event.
Examples and documentation

To access the SDK for direct viewing and to import to your IDE:

1. Navigate to `<install-dir>\Micro Focus\ReflectionZFE\sessionserver\sdk\java`.
2. In the SDK directory, access:
   - \javadoc - This directory contains JavaDoc files for direct viewing.
   - \samples - This directory contains Java sources for direct viewing.
   - \zfe-sdk.jar - The JAR file contains the Java classes to import into your IDE.
   - \zfe-sdk-javadoc.jar - The JAR file contains JavaDoc files to import into your IDE.

Using the ZFE Connector for Windows

Reflection ZFE Connector for Windows is a separate installation which you can find on the Micro Focus download site. Using the Reflection ZFE Connector for Windows, you can interact with ZFE host sessions in your .NET application or within Visual Basic for Applications.

The API documentation is available in your installation directory (`<install dir>\sessionserver\sdk\csharp\apidocs\index.html`) as well as online.

Here are a few things to keep in mind as you prepare to install:

- Two install platforms are available: a 32-bit version and a 64-bit version. Depending on which one you install, the default base install path will be `C:\Program Files (x86)\Micro Focus\ReflectionZFE\Connector for Windows` or `C:\Program Files\Micro Focus\ReflectionZFE\Connector for Windows`.
- The installation platform you choose also determines the solution platform in which you can develop. For example: If you have installed the 32-bit version of Microsoft Office® and want to use Visual Basic for Applications with the connector, then you must install the 32-bit version of the Reflection ZFE Connector for Windows.
- API documentation is available here: `<install dir>\sessionserver\sdk\csharp\apidocs\index.html`.
- .NET 4.5.2 is required.

Examples and connector documentation

Documentation is available to reference from your IDE. There are also samples to help you take advantage of the connector. Both are located here:

1. Navigate to the install directory. In a default install, either `C:\Program Files (x86)\Micro Focus\ReflectionZFE\Connector for Windows` or `C:\Program Files\Micro Focus\ReflectionZFE\Connector for Windows` depending on your platform.
2. In the Connector for Windows directory you will find:
   - MicroFocus.ZFE.Connector.dll - a .NET Framework assembly to reference in your C# or .NET project.
   - MicroFocus.ZFE.Connector.tlb - a Type Library to use in your COM or Visual Basic for Applications project.
Using the connector with Microsoft Visual Studio

If you are using Microsoft Visual Studio to develop applications, keep these things in mind:

- When using Microsoft Visual Studio with Reflection ZFE Connector for Windows, make sure your solution platform is set to either x86 or x64, depending on your installation. Because of the native components used within the Reflection ZFE Connector for Windows SDK, the Any CPU platform is not supported. Use the Configuration Manager for your Visual Studio Solution to create a platform for x86 or x64.
- When adding a reference to the Reflection ZFE Connector for Windows library, Visual Studio may set the Copy Local reference property to True. This should be set to False so that the library and its dependencies are executed from the SDK install directory.

Using the ZFE JavaScript API

Using JavaScript in a browser you can embed the ZFE web client in a web page. Your end users, by accessing a common web page, can interact with the web client and connect to the host application providing the ability to:

- Programatically interact with host sessions.
- Run it “headlessly”, meaning you can access all its functionality without having a visible interface embedded in the web page.

There are getting started and other tutorials available for your use. The API documentation, along with the tutorials, is available online and in <install dir>\sessionserver\sdk\javascript.

- Using the ZFE Connector for Windows
- Using the ZFE Java SDK

Extending the ZFE Web Client

You can update, modify, and customize the presentation of the ZFE web client by using your own HTML, CSS, or JavaScript from within the browser.

You can take advantage of extensions to make visual changes to the web client and to customize the application. The web client hosts your custom HTML or CSS code, making it easy to modify and support.

Learn more about:

- Adding an extension
Adding an extension

Before proceeding keep in mind that although ZFE provides the ability to plan and use custom code, the code itself must be supported by the team that produced it.

**WARNING:** During a product upgrade extensions are disabled. This means that, after an upgrade, you must verify that the product is working as expected without extensions, and then re-enable the extensions using the steps to add custom code.

When you add extensions to the ZFE web client, the modifications are visible to all your users and apply to all sessions.

**To add an extension**

1. Open `<install_dir>/sessionserver/microservices/zfe/service.yml`.
2. Change the value of the `SPRING_PROFILES_ACTIVE` property from `default` to `extensions-enabled`.
3. Restart the session server.
4. Create `<install_dir>/sessionserver/microservices/zfe/extensions/client/index.html` to act as your entry point. This is where you add any HTML, CSS, or JavaScript (including references to external scripts).

**Making extensions available without client authentication**

Files within the `/client` directory are protected using the level of authentication you selected in MSS.

**To share files without requiring authentication:**

Create `<install_dir>/sessionserver/microservices/zfe/extensions/public/`. Place your code in that directory, calling it using the URL `/zfe/public/*`.

**Extension sample**

In this example, once extensions are enabled (see Step 2 above), you can add some custom CSS and JavaScript code to change the menu label font color and print text to the JavaScript console.

You will create three files; custom.css, custom.js, and index.html.

**Step 1.**

Locate `index.html`, which you created in step 4 above. This is where you will be placing your extension files, creating an entry point:

```html
<!-- Define the link to the external style sheet -->
<link href="client/custom.css" rel="stylesheet">
<!-- Define the external JavaScript file -->
<script src="client/custom.js"></script>
```

**Step 2.**

Change the default black menu labels to orange:
Create custom.css to change the color to orange:

/* Change link text to Orange */
a span {
    color: #ff5d28;
}

Step 3.

Create custom.js to send text to the JavaScript console:

//Print message to the JavaScript console
console.log('Hello World!');

Step 4.

When the files are in place, <install_dir>/sessionserver/microservices/zfe/extensions/client/index.html, the results should look like this:

And the “Hello World” text is visible in the JavaScript console:

- Improving Connection Times on Non-Windows Platforms
- Known Issues

Copying Sessions between Management and Security Servers

You can copy and convert Reflection for the Web sessions and make them available to another Management and Security Server (MSS) and Reflection ZFE.

**NOTE:** In the following procedure the Management and Security Server you are copying sessions from is the source, and the Management and Security Server you are copying to is the destination.

To copy sessions from the source server to the destination server follow these steps:

1. Stop the destination MSS server, if necessary.
2. On both source and destination MSS servers, open SessionDS.xml, located:
   - On Windows: C:\ProgramData\Micro Focus\MSS\MSSData
   - On Linux: /var/opt/microfocus/mss/mssdata
3. In the source XML file, locate the OBJECT_ARRAY element.
4. Still in the source XML file, under OBJECT_ARRAY, locate and copy the Reflection for the Web child Session elements.
5. Open the destination XML file and paste them under the destination file's OBJECT_ARRAY element.
6. Still in the destination file, locate the OBJECT_ARRAY size attribute that corresponds to the number of sessions. Increase that value by the number of session elements you added. For example, if you pasted six Session elements in the destination file and the existing OBJECT_ARRAY size attribute value is 4; increase the value by six. The size attribute should now be ten. And you should now have 10 Session elements listed under the OBJECT_ARRAY element.
7. Session names must be unique. Check the destination file for duplicate session names. You can find session names in the Session child element, SessionName.
Copy the configuration files for every session added to SessionDS.xml from the source to the destination server. The names of the configuration files are located under the Session element in the child element, configuration. The files themselves are located:

- On Windows: C:\ProgramData\Micro Focus\MSS\MSSData\deploy\dyncfgs
- On Linux: /var/opt/microfocus/mss/mssdata/deploy/dyncfgs

If you stopped the destination MSS server, restart it. Open the Administrative Console. You should see all your copied Reflection for the Web sessions in the Manage Sessions list.

The next step is to save the Reflection for the Web session as a Reflection ZFE session. In Manage Sessions, right-click the session you want to export. Session types are identified by an icon in the Type column.

See Export a Reflection for the Web session for information on saving a Reflection for the Web session to a Reflection ZFE session in the Administrative Console.

Connecting using HTTP

If you do not have a trusted certificate in place, you can configure Reflection ZFE to use HTTP. This configuration is not secure and should be used only when no other option is available.

<table>
<thead>
<tr>
<th>Connecting to...</th>
<th>Do this...</th>
</tr>
</thead>
<tbody>
<tr>
<td>An existing remote MSS Administrative Server</td>
<td>1. During the Reflection ZFE installation, after you accept the license agreement and choose a destination directory, select Use remotely hosted MSS. Click Next.</td>
</tr>
<tr>
<td></td>
<td>2. Enter either the host name, DNS name, or IP address.</td>
</tr>
<tr>
<td></td>
<td>3. Change the port from 443 to 80.</td>
</tr>
<tr>
<td></td>
<td>4. Select HTTP and complete the installation process.</td>
</tr>
<tr>
<td>The MSS Administrative Server that is installed with Reflection ZFE</td>
<td>1. Select Install MSS and follow the installation instructions.</td>
</tr>
<tr>
<td></td>
<td>2. Clear the Perform this action option and click Finish.</td>
</tr>
<tr>
<td></td>
<td>If this option is not disabled, you can open &lt;install-directory&gt;\Micro Focus\ReflectionZFE\sessionserver\conf\container.properties in a text editor and change 443 to 80 in the following line: management.server.url=<a href="http://yourmachine:80/mss">http://yourmachine:80/mss</a></td>
</tr>
<tr>
<td></td>
<td>If this option is not cleared, an internal error is generated and you will be asked to contact your system administrator.</td>
</tr>
<tr>
<td></td>
<td>3. Restart the Reflection ZFE Session Server service.</td>
</tr>
</tbody>
</table>
Configuring User Names when Using Anonymous Access Control

Users need access to their macros, user configurations, and other personalized settings whether they are authenticated anonymously through Management and Security Server or not. Reflection ZFE uses user names to store user-specific information; but what happens when users are anonymously authenticated through Management and Security Server’s access control interface?

In a default environment, Reflection ZFE uses the session id of the HTTP session as the value for the user name. While this user name is unique for each browser session, it changes over time and when MSS is configured in anonymous mode, in order to consistently retrieve user settings, all users of that Reflection ZFE session necessarily share the same settings.

However, Reflection ZFE supports a number of ways that, as an administrator, you can configure a unique identifier for each user so their customized settings can be stored and retrieved.

**NOTE:** These configuration modifications do not alter the security considerations of using Management and Security Server in anonymous mode.

**Configuration options**

There are four different configuration options you can choose from when configuring user name identifiers. You must restart the Reflection ZFE session server before any changes take effect.

- **To use an HTTP request cookie value as the user name**
  
  Add the following lines to `<session-server>/conf/container.properties`:
  ```
  zfe.principal.name.provider=com.microfocus.rzfe.webclient.security.rsg.CookieKeyAnonymousPrincipalNameProvider
  zfe.principal.name.identifier=<the-cookie-key-to-be-used>
  ```

- **To use an HTTP request header value as the user name**
  
  Add the following lines to: `<session-server>/conf/container.properties`:
  ```
  zfe.principal.name.provider=com.microfocus.rzfe.webclient.security.rsg.HeaderKeyAnonymousPrincipalNameProvider
  zfe.principal.name.identifier=<the-header-key-to-be-used>
  ```

- **To use an HTTP request URL parameter as the user name**
  
  Add the following lines to: `<session-server>/conf/container.properties`:
  ```
  zfe.principal.name.provider=com.microfocus.rzfe.webclient.security.rsg.UrlParameterAnonymousPrincipalNameProvider
  zfe.principal.name.identifier=<the-url-parameter-key-to-be-used>
  ```

- **To use the client IP address as the user name**
  
  Add the following line to: `<session-server>/conf/container.properties`:
  ```
  zfe.principal.name.provider=com.microfocus.rzfe.webclient.security.rsg.RemoteAddrAnonymousPrincipalNameProvider
  ```
Troubleshooting the configuration

If any of your users experience problems when connecting to a Reflection ZFE web application after you have made the configuration changes, check the following:

- Users experience a 503 Service Unavailable message when connecting to a Reflection ZFE web application. First check the log file (<session-server>/logs/server.log), then:
  -- If the log file contains this message: “Unable to create AnonymousPrincipalNameProvider instance for class...”, then the zfe.principal.name.provider property is probably mis-typed. Check the spelling and letter case to remedy this issue.
  --If the log file contains this message: “zfe.principal.name.identifier is not defined”, then the property is missing. Ensure the property is defined to remedy this issue.

- Users are unable to properly authenticate.
  Users should receive an error message indicating the initial HTTP request to the Reflection ZFE web application did not contain the required information.

Accessing Reflection ZFE using the IIS Reverse Proxy

This note describes how to use the IIS Reverse Proxy with Reflection ZFE. In order to comply with Common Criteria security requirements, it is necessary to place the Reflection ZFE server behind a proxy in this manner.

Prerequisites

- Internet Information Services (IIS) 8.0 or later is required.
- The IIS WebSockets protocol must be enabled. See IIS 8.0 WebSocket Protocol Support for information on how to enable this protocol.
- IIS Application Request Routing (ARR) 3.0 or later is required.
- The IIS URL Rewrite module must be installed.

Configure the IIS Reverse Proxy for Reflection ZFE

This example illustrates configuring an IIS server with the IP address of 192.168.1.1 to proxy connections to the Reflection ZFE Session Server at http://10.10.10.1:7070.

Configuring IIS

1. Launch the Internet Information Services (IIS) Manager, navigate to the web site you want to use, and open the URL Rewrite feature.
2 Choose the Add Rule(s) action and add a Reverse Proxy rule.

![Add Rule(s) dialog]

3 For the inbound rule, enter the Reflection ZFE server’s IP address or host name and port. For example, if the Reflection ZFE session server is on the same machine as IIS and is using its default port, enter localhost:7070.

After you create the rule, edit it and add a condition: {REQUEST_URI} matching the pattern (.*(/
|ze.*)). This rule is necessary to ensure that native IIS content is accessible and not redirected to the specified host and port.

![Condition settings]

4 Check the outbound rule Rewrite the domain names... and enter the host name or IP address of the IIS server in the To: box

5 Click OK to create the new Reverse Proxy Rule.
Configuring Reflection ZFE

In order to proxy connections, the IIS URL Rewrite module must inspect and rewrite the web pages and WebSocket connections that pass through the proxy. For rewriting to succeed, these items must be sent in an uncompressed form. Note that, if configured, compression will still occur from the IIS server to the client’s browser. The Reflection ZFE session server must also be configured to allow WebSocket connections to originate from the proxy.

1. Open container.properties in a text editor. The default location for this file is: <install dir>/sessionserver/conf.

2. Add the following lines to container.properties:

```java
websocket.compression.enable=false
server.compression.enabled=false
websocket.allowed.origins=http://<IIS server name or IP address>
```

For example: `http://192.168.1.1`

Save changes to the file. The Allowed Origins property is a comma-delimited list of URLs. If web clients will be connecting to your website using an HTTPS connection, adjust the URL accordingly. If both secure and non-secure connections will be used, use both URLs as the value: `websocket.allowed.origins=http://192.168.1.1,https://192.168.1.1`. To avoid errors, make sure that all possible address formats are included in the Allowed Origins list.

3. Restart the web site and restart the Reflection ZFE session server and test the proxy by connecting to: `http(s)://192.168.1.1/zfe`

Troubleshooting

If you receive web server errors, enabling detailed errors may help diagnose the problem. In the IIS Manager, open the Error Pages feature and check Detailed errors:

![Edit Error Pages Settings](image)

Typically errors in the 5XX range are caused by issues with compression being enabled or mistakes in the Allowed Origins value.
If the IIS proxy will be connecting to the Reflection ZFE session server with HTTPS, then the certificate used with the session server must be trusted by the IIS server. If the Reflection ZFE session server is using a self-signed certificate, this certificate must be added to the Windows trust store. If the Reflection ZFE session server is using a signed certificate, then the signer must be a trusted CA.

**Improving Connection Times on Non-Windows Platforms**

To improve connection times on non-Windows platforms, follow these steps after installing the Reflection ZFE session server, particularly when the system is virtualized or otherwise headless:

1. Stop the Reflection ZFE session server service.
2. Open the `<Reflection ZFE installation folder>/sessionserver/conf/container.conf` file in a text editor.
3. Locate this line, and edit as follows:
   ```
   #wrapper.java.additional.x=-Djava.security.egd=file:///dev/urandom
   ```
   - Remove the # to uncomment the line.
   - Replace x with `<n+1>`, where `<n>` is the highest number noted in the other `wrapper.java.additional.<n>` lines.
   - Save the file.
4. Restart the Reflection ZFE session server service.

**Known Issues**

These issues have been identified in previous releases and are known issues.

- Browser issues
- Host specific issues

**Browser issues**

The following notes are specific to different web browsers.

- Recommended browsers
- Key mapping issues with different browsers

**Recommended browsers**

It is highly recommended that you use Google Chrome or Mozilla Firefox. While Reflection ZFE supports Microsoft Internet Explorer (IE) 11, there are known performance issues with Internet Explorer’s JavaScript engine that may negatively affect the end user experience with Reflection ZFE.

These issues have been identified and have remedies, however the easiest solution is to use a different browser.
Internet Explorer Unable to Play Recorded Reflection ZFE Macros

When using certain older versions of Microsoft Internet Explorer (IE) web browser with Reflection ZFE, attempts to playback macros may fail with an error. The error message reads: *Macro Error: Error transpiling macro code: TypeError: unknown: Circular reference in value argument not supported.*

This is a problem with this version of Internet Explorer and JavaScript. It may be possible to avoid this error if you delete the createMacro() function and replace it using JavaScript Promises (for example, then() ).

Because this issue is specific to early versions of Internet Explorer, the easiest solution to this problem is to use a different browser (Chrome or Firefox) or a more recent version of Internet Explorer. You can successfully play back macros using Internet Explorer version 11.0.9600.18161, update version 11.0.27. Run Windows Update to update Internet Explorer.

HTTPS connections between Apple iOS mobile devices and the Reflection ZFE session server

Reflection ZFE users cannot connect to a session server over HTTPS from their Apple iPad when using a self-signed certificate. If feasible, the quickest solution is to use HTTP instead of HTTPS.

If HTTPS is needed, you have the following options:

- Obtain a valid certificate signed by a trusted CA and install it on the session server.
- Find an alternate browser that will accept the self-signed certificate. See Browser and operating system support for a list of supported browsers.
- Leverage a custom certificate authority:
  1. Create a custom CA, CA root certificate, and a server certificate signed by that CA’s root certificate.
  2. Install the server certificate on the session server.
  3. Install the custom CA root certificate on the iPad by means of a profile. The iPad should now accept the server certificate as it was signed by a “trusted CA”.

For a list of CAs trusted by Apple iOS, see Lists of available trusted root certificates in iOS (https://support.apple.com/en-us/HT204132).

Internet Explorer Displays Blank Screens

When using the Microsoft Internet Explorer (IE) web browser with Reflection ZFE (RZFE) or Host Access Management and Security Server (MSS), you may see a blank screen instead of the expected session.

When using Microsoft Internet Explorer to access Reflection ZFE sessions or Host Access Management & Security Server, you may experience issues such as the following:

- Reflection ZFE renders properly for some URLs and not others (a blank screen is displayed). The behavior varies depending on whether the ZFE session is using an IP address, short hostname, or fully-qualified name.
- In MSS, you can’t create or open a ZFE session unless that session is on the same server as MSS. A blank screen displays where you expect to see the session.

Explanation
This issue is specific to the way Internet Explorer toggles various settings depending on its interpretation of website security. The settings in question are Compatibility View and Third-party Cookies. Depending on what “zone” Internet Explorer determines your web site to be in, these settings need to be either enabled or disabled. Internet Explorer bases its determination on the site URL. For example, if the server name in the URL does not contain dots (for example, http://mycorporateserver/mss/AdminStart.html), Internet Explorer assumes the address belongs in the Local Intranet zone. If it does, the site is assigned to the Internet zone.

<table>
<thead>
<tr>
<th>Zone</th>
<th>Internet Explorer Default Settings</th>
</tr>
</thead>
<tbody>
<tr>
<td>Local Internet Zone</td>
<td>Compatibility View enabled (not desired)</td>
</tr>
<tr>
<td></td>
<td>Third-party Cookies enabled (desired)</td>
</tr>
<tr>
<td>Internet Zone</td>
<td>Compatibility View disabled (desired)</td>
</tr>
<tr>
<td></td>
<td>Third-party Cookies disabled (not desired)</td>
</tr>
</tbody>
</table>

While it is possible for a website to override Compatibility View by specifying Document Mode with an X-UA-Compatible meta HTML tag, and Reflection ZFE does use that particular mode, MSS does not. Thus, if a Reflection ZFE server and a Management and Security Server are both in the Local Intranet zone (with default Compatibility View enabled), it is likely that Reflection ZFE would still perform correctly, but MSS would not. See http://blogs.msdn.com/b/ieinternals/archive/2012/06/05/the-local-intranet-security-zone.aspx for more information.

**Solution**

To use Internet Explorer 10 or 11 with ZFE and MSS servers, you need:

- Compatibility View disabled
- Third-party Cookies enabled

You need to determine what zone your web site is in and then make the necessary adjustments to the Internet Explorer settings. Because Internet Explorer can be configured in so many different ways depending on your situation, it is hard to provide one solution for successfully using Internet Explorer with Reflection ZFE and MSS. These are some possible configurations to follow:

- If both RZFE and MSS are in the Internet zone, manually add the RZFE server to the Local Intranet or Trusted Sites zone (Internet Options > Security > Local intranet > Sites). Use fully qualified host names or IP addresses.
- If both servers are in the Internet zone, change the default behavior for that zone and enable Third-party Cookies (Internet Options > Privacy > Advanced > Override automatic cookie handling).
- If both servers are in the Local Intranet zone, change the default behavior for that zone and disable Compatibility View (Tools > Compatibility View settings).

**Key mapping issues with different browsers**

Certain keys on a numeric keypad and some browser-specific keys cannot be mapped. For example, in Chrome, Ctrl+n and Ctrl+w cannot be mapped.

**Host specific issues**

The following are issues that are specific to different host types.
Displaying the Euro character

If the EURO character does not display correctly on the terminal screen, talk to your system administrator to make sure the host character set for the session is setup correctly. By default, Reflection ZFE uses a character set which does not support the Euro character (€). To display the Euro character, change the character set to one that supports the Euro character.

Issues encountered with VT hosts

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Performance issues</td>
<td>♦ Heavy text output, such as form &quot;Is-IR&quot; may cause slow performance</td>
</tr>
<tr>
<td></td>
<td>♦ Scrolling regions may appear slow or choppy</td>
</tr>
<tr>
<td></td>
<td>♦ Cursor movement may be slow or choppy</td>
</tr>
<tr>
<td></td>
<td>♦ Internet Explorer is particularly slow, and performance degrades further when used for rows and columns.</td>
</tr>
<tr>
<td>Character sets</td>
<td>♦ Graphical characters and some character sets are not supported.</td>
</tr>
<tr>
<td></td>
<td>♦ Some non-English characters may cause the terminal display to freeze.</td>
</tr>
<tr>
<td>Other VT issues</td>
<td>♦ Insert/delete column (DECIC, DECDC) may fail.</td>
</tr>
<tr>
<td></td>
<td>♦ VT400 will not recognize DECSCL.</td>
</tr>
</tbody>
</table>

Field outlines in 3270 sessions

The 3270 attributes for field outlines are not fully supported. Reflection ZFE currently supports underline and overline; however, left vertical line, right vertical line, and combinations of the four line types are not yet supported.
